Abstract

Nitroxyl (HNO), a potential heart failure therapeutic, is a reactive species that spontaneously dimerizes to yield hyponitrous acid, which dehydrates to generate nitrous oxide (N₂O). Due to its inherent chemical reactivity, HNO cannot be used directly, and therefore, donors are required for its *in situ* generation. Here, we report *N*-substituted hydroxamic acids with pyrazolone leaving groups (**NHPY**) and *O*-substituted hydroxamic acids with pyrazolone leaving groups (**OHPPY**) as novel precursors to nitrosocarbonyl intermediates, which subsequently provide HNO. Nitrosocarbonyls are transient electrophiles that react with nucleophiles, including water, to produce HNO. We found that pyrazolones are efficient nitrosocarbonyl traps under physiologically relevant conditions, undergoing an *N*-selective nitrosocarbonyl aldol reaction. This trapping reaction has been used to confirm the involvement of nitrosocarbonyls as intermediates in the observed chemistry.

Time-resolved infrared (TRIR) spectroscopy is a powerful tool for studying photochemically generated reactive intermediates in solution. Applying this technique, we examined the reactivity of a photo-generated nitrosocarbonyl intermediate with a pyrazolone and reported the rate constant for this trapping reaction.

Advisor: Professor John P. Toscano

Readers: Professor Thomas Lectka

Professor Kenneth D. Karlin

Acknowledgments

I would like to thank Professor John P. Toscano for granting me the opportunity to work in his research group. He taught me how to think, independently, as a scientist, and gave different opportunities to challenge myself. I sincerely thank him for being such a thoughtful advisor.

Also, I would like to thank Professor Thomas Lectka and Professor Kenneth D. Karlin for serving on my thesis committee. I thank my lab mates: Dr. Gizem Keceli, Dr. Daryl A. Guthrie, Dr. Tyler A. Chavez, Dr. Christopher L. Bianco, Dr. Vinayak Khodade, Hyunah Cho, Blaze Pharoah, Christopher Chang, Zachary A. Zilber, and Robert P. Lesko, for very helpful discussions and all the scientific work we had in last five years.

Most of all, my sincere thanks go to my dad. I wouldn't be who I am today without his encouragements and thoughtfulness. He is always in my heart. Also, I am very grateful to my mom for supporting me with my decisions. She is a true example of kindness and patience. I want to thank my brother and sister for always being so helpful to me, and supporting me through ups and downs of my life. I would also like to thank my parents-in-law for their constant support.

I would like to dedicate this thesis to my love, Ashkan. Thanks for everything!

Chapter 1.

Introduction

1.1 Nitroxyl (Azanone, HNO)

Nitric oxide (NO) is a biological signaling agent that has been shown to modulate numerous physiological processes.¹⁻³ This endogenously produced small molecule plays an important role in blood pressure control, the immune response and neurotransmission.^{2,4}

Peroxynitrite (ONOO⁻), nitrite (NO₂⁻), and nitrogen dioxide (NO₂) can be formed through oxidation of NO in certain aerobic and biological environments.⁵ Many reports have demonstrated the importance of these molecules as biological effectors.⁶ The role of NO was preliminary thought to be as an oxidative agent, so research mainly studied NO species with higher oxidation states, and less consideration focused on reduced species such as the one-electron reduced form of NO, nitroxyl (HNO).

Although the endogenous generation of NO is well established, the endogenous generation of HNO has not been demonstrated. HNO has been shown to enhance both vasorelaxation and myocardial contractility, which makes it a potential therapeutic for treatment of heart failure.⁷⁻¹¹

There are some proposed biosynthetic pathways that suggest the possibility of endogenous generation of HNO. Nitric oxide synthases (NOS) is an enzyme that converts arginine to citrulline and NO in presence of the cofactor tetrahydrobiopterin (THB).¹² Generation of HNO using isolated neuronal NOS has been demonstrated in the absence of THB.¹³ Also, generation of HNO has been shown by oxidation of hydroxylamine (NH₂OH) with heme-containing proteins.¹⁴ Interconversion of NO and HNO in presence of superoxide dismutase (SOD) is another possible pathway that suggests the endogenous generation of HNO.¹⁵ Recently, the reaction of hydrogen sulfide (H₂S) with NO potentially to form thionitrous acid (HSNO) has attracted attentions.^{16,17} Upon reaction with H₂S, HSNO can produce HNO. Although these results may demonstrate the possibility of endogenous generation of HNO, more investigations are required to provide direct evidence for *in vivo* HNO formation.

A complication of studying HNO chemistry is its high reactivity. As shown in Scheme 1-1, HNO spontaneously dimerizes ($k = 8 \times 10^6 \text{ M}^{-1}\text{s}^{-1}$) to hyponitrous acid (HON=NOH), which subsequently dehydrates to produce nitrous oxide (N₂O).¹⁸ Detection of N₂O has served as a marker for the presence of HNO.

Scheme 1-1. HNO Dimerization

The pK_a of HNO has been evaluated to be 11.4.^{18,19} Thus, under physiological conditions HNO exists mostly in its protonated form. The deprotonation of HNO, which is a ground state singlet,^{20,21} to generate NO^- , with a triplet ground state,^{22,23} is presumed to be quite slow due to the spin-forbidden nature of this process.

One major target for biochemical reactivity of HNO appears to be thiols (Scheme 1-2). Depending on the concentration of thiol, HNO reactivity results in the formation of sulfinamides or disulfides.^{24,25} The second-order rate constant for reaction of HNO with glutathione and cysteine were determined to be $2 \times 10^6 \text{ M}^{-1}\text{s}^{-1}$ and $5 \times 10^5 \text{ M}^{-1}\text{s}^{-1}$, respectively. The pK_a of the reacting thiol is thought affect the trapping rate, with thiols of lower pK_a values reacting faster with HNO.²⁶

Scheme 1-2. HNO Reactivity with Thiols

Recently, the reaction of carbon based nucleophiles with HNO has been studied under physiological conditions.²⁷⁻²⁹ Also, transition metal centers are known to be targets for HNO in biological systems. HNO reduces ferric hemes to

generate ferrous heme-nitrosyl complexes through reductive nitrosylation reactions.³⁰⁻³³ The same reductive properties of HNO with other metals such as copper (Cu)³⁴ and manganese (Mn)³⁵ have also been reported.

1.2 HNO Donors

As discussed above, HNO is a very reactive molecule and rapidly dimerizes through an irreversible process, so donors are needed for the *in situ* generation of HNO. Angeli's salt (**AS**) is a well-known HNO donor that was first reported in 1896.³⁶ Piloty's acid (**PA**) is another HNO donor that was reported in the same year.³⁷ There are also other HNO donors reported in literature (Figure 1-1), including primary amine based diazeniumdiolates, such as **IPA/NO**,^{38,39} acyloxy nitroso compounds (**AcON**)^{40,41}, *N*-hydroxycyanamide,⁴²⁻⁴⁵ *N*-substituted hydroxylamine with pyrazolone leaving groups (**HAPY**),²⁷ *N*-substituted hydroxylamines with barbituric acid leaving groups (**HABA**),²⁸ and nitrosocarbonyl (**NC**) precursors^{46,47}.

Figure 1-1. Representative examples of HNO donors.

1.2.1. Angeli's Salt

Angeli's salt (**AS**) is an oxygen-based diazeniumdiolate, and efficient HNO donor with a half-life of ~ 3 min under physiological conditions.^{48,49} **AS** is the most prevalent donor that has been used to study HNO chemistry and pharmacology. Decomposition of **AS** involves protonation followed by tautomerization to produce HNO and nitrite as the end products.⁵⁰ **AS** becomes an NO donor at pH < 4 and the decomposition mechanism is through tautomerization to a higher energy species⁵¹ as shown in Scheme 1-3. Under physiological conditions, **AS** is an efficient HNO donor, but modification of its structure to access corresponding HNO donors with longer half-lives has not yet been reported. Thus, other donors are required to investigate the physiological effects of chronic delivery of HNO.

Scheme 1-3. Decomposition Pathways of Angeli's Salt

HNO producing pathway:

NO producing pathway:

1.2.2. Amine-Based Diazeniumdiolates

Keefer and co-workers have reported a range of secondary amine-based diazeniumdiolates as efficient NO donors in biological studies.⁵²⁻⁵⁵ Miranda and colleagues have investigated primary amine-based diazeniumdiolates as potential

HNO donors.^{38,39} Depending on pH and amine backbone, these primary amine derivatives can serve as both HNO and NO donors. The isopropyl amine derivative **IPA/NO** is a well-known primary amine-based diazeniumdiolates that under physiological conditions releases equimolar amounts of HNO and NO as shown in Scheme 1-4.

Scheme 1-4. Decomposition Pathways of IPA/NO

1.2.3. Piloty's Acid Derivatives

Piloty's acid (**PA**) was first synthesized by the German chemist, Oskar Piloty, in 1896.³⁷ **PA** is an *N*-substituted hydroxylamine derivative with a sulfinate as the leaving group, and can generate HNO under basic conditions (Scheme 1-5).^{56,57} The first step for decomposition is the deprotonation of hydroxylamino group.^{56,58,59} Doctorovich and co-workers studied different **PA** derivatives with various pK_a values. It was shown that the highest rate of HNO generation was at pH values where the **PA** derivatives is fully deprotonated.⁶⁰ This suggests a barrier for HNO release from anionic **PA**, which could be reflected in reversible HNO generation as sodium benzenesulfinate is known to slow the decomposition rate of **PA**. Under physiological conditions, **PA** is oxidized and becomes an NO donor.⁶¹

Scheme 1-5. Decomposition Pathways for Piloty's Acid

To promote HNO generation from Piloty's acid derivatives, bulky groups or electron withdrawing groups have been added to the phenyl ring.⁶²⁻⁶⁴ Electron withdrawing groups can decrease the pK_a value of the donor and stabilize the sulfinate leaving group, thereby facilitating HNO generation. Interestingly, crystallographic analysis confirmed that **PA** derivatives with electron withdrawing groups have shorter N-O bond distances, which may suggest more facile HNO generation.⁶⁰

Our lab has synthesized a variety of **PA** derivatives including 2-bromo-*N*-hydroxybenzenesulfonamide (2-bromo-Piloty's acid).⁶² This compound is an excellent HNO donor with the half-life of 2.4 min under physiologically relevant conditions.

1.2.4. Acyloxy Nitroso Compounds

Acyloxy nitroso compounds (**AcON**) can hydrolyze to release HNO (Scheme 1-6).⁶⁵⁻⁶⁶ **AcON** compounds can be synthesized via oxidation of oximes in the presence of carboxylic acids. The rate of HNO generation depends on pH and the ester group structure. Based on decomposition studies, the chemistry of **AcON** compounds is more complicated than preliminarily expected. Upon hydrolysis of the ester group, as shown in Scheme 1-6, an alpha hydroxyl nitroso intermediate is

formed, which can further decompose to release HNO (Path A). In presence of thiols, formation of hydroxysulfenamide, disulfide, and hydroxylamine are reported, suggesting the generation of HNO. However, a non HNO-producing pathway, direct reaction of the thiolate with the acyloxy nitroso compound (Scheme 1-6, Path B), can compete with HNO generation forming disulfides as identical end products. Thus, the decomposition of **AcON** compounds can go through competing pathways.

Scheme 1-6. Decomposition Pathways of Acyloxy Nitroso Compounds

1.2.5. Cyanamide

Aldehyde dehydrogenase (ALDH) is an enzyme that catalyzes the conversion of acetaldehyde to acetate. After consumption of alcohol, inhibition of ALDH causes acetaldehydemia. HNO can inhibit ALDH via its reaction with the active site cysteine residue.⁴²⁻⁴⁵ Cyanamide is an alcohol deterrent that has been used in Europe, Canada, and Japan and can release HNO upon metabolic activation (Scheme 1-7). *N*-hydroxycyanamide is the proposed intermediate that can be formed upon bioactivation of cyanamide. This *N*-substituted hydroxylamine derivative is

unstable, and decomposes to either produce HNO or upon oxidative metabolism, generates nitrosyl cyanide, which further can hydrolyze and release HNO (Scheme 1-7). Beside HNO, four other products are formed: HCN, HNO₂, CO₂, and NH₃. Following derivatization of cyanamide compounds, *N,O*-dibenzoyl derivatives of *N*-hydroxycyanamide **1** have been synthesized (Scheme 1-7), but this compound generates HNO only in presence of esterase or base.⁶⁷

Scheme 1-7. Cyanamide Decomposition Pathways

1.2.6. Hydroxylamines with Carbon Based Leaving Groups

Recently, Toscano et al. have reported three new classes of highly tunable HNO donors based on hydroxylamino Meldrum's acid **HAMA**, hydroxylamino barbituric acid **HABA**, and hydroxylamino pyrazolone **HAPY** scaffolds.²⁷⁻²⁹ These compounds are examples of *N*-substituted hydroxylamines with carbon-based leaving groups. Employing these donors, the idea is to generate HNO along with a stable carbanion at neutral pH. The mechanism of decomposition is through deprotonation of the hydroxylamino moiety and subsequent HNO generation

(Scheme 1-8). Beside the importance of donors pK_a that significantly affect the rate of HNO release, the acidity of the leaving group has strong impact on the stability of these donors under physiological conditions.

After decomposition of **HAMA** compounds, it is expected that HNO be generated with an equimolar amount of Meldrum acid. Meldrum acids have low pK_a values because upon deprotonation, delocalization of the lone pair of electrons through the ring can effectively stabilize the carbanion. However, the carbonyls of Meldrum acids ring are prone to nucleophilic attack.⁶⁸ Based on reported evidence, formation of acetone upon hydrolysis of **HAMA** compounds competes with HNO formation, which may limit the application of this class of compounds.²⁹

Scheme 1-8. HNO Release from HAMA, HABA, and HAPY compounds

Barbituric acids are stable to hydrolysis, and have low pK_a values. The initial report presented an *N*-substituted hydroxylamine with a barbituric acid leaving group ($R^1 = \text{Me}$, $R^2 = \text{C}(=\text{NOMe})\text{Me}$) that has a short half-life (0.7 min) and excellent HNO yield (> 95%) upon decomposition. However, there is a non-HNO producing pathway that competes with HNO release for these barbituric acid derivatives.

Based on reported experiments, it is possible for some barbituric acid derivatives to rearrange to hydantoin, and therefore, inhibit HNO formation. Following decomposition of different **HABA** compounds, the propensity to rearrangement was examined in order to develop strategies that favor HNO generation. It has been shown that 1,3-unsubstituted barbituric acid derivatives ($R^1 = H$) do not undergo this rearrangement, and the barrier to rearrangement can be increased by modification of R^2 substitutions. Using these strategies, an extensive series of **HABA** compounds with various half-lives (19-107 min) have been reported.²⁸

The **HAPY** compounds are efficient HNO donors with no observed rearrangement of the pyrazolone ring. Additionally, the reported pyrazolone derivatives were shown to be stable to hydrolysis, and therefore, did not undergo non-HNO producing pathways. A correlation between half-lives of **HAPY** compounds and donor pK_a values was found. **HAPY** compounds with low pK_a values are short-lived HNO donors. With these findings, Toscano et al. reported different **HAPY** derivatives with excellent HNO yields and various half-lives (4-5674 min) under physiologically relevant conditions.

1.2.7. Nitrosocarbonyl Precursors

Nitrosocarbonyls are reactive electrophiles that can react with nucleophiles, including water, to generate HNO (Scheme 1-9).^{46,69-71} These intermediates can be generated by a variety of chemical processes including oxidation of hydroxamic acids using oxidants such as periodate salts,⁷² lead and silver oxides,⁷³ and Dess-Martin periodinane.⁷⁴ Other methods for nitrosocarbonyl generation include

thermal fragmentation of Diels-Alder adducts,^{46,71,75} oxidation of nitrile oxide,^{76,77} photocleavage of 1,2,4-oxadiazole-4-oxides,⁷⁸ and the rearrangement of nitrosocarbenes.⁷⁹⁻⁸² In general, these methods are not suitable for HNO generation under physiological conditions. *N,O*-bis-acylated derivatives, such as *N,O*-dibenzoyl-*N*-hydroxycyanamide, are other examples of nitrosocarbonyl precursors. As mentioned in Section 1.2.5., enzymatic or basic treatments for HNO release from this compound are required, which potentially limits the scope of HNO generation under physiological conditions.⁶⁷ Recently, Toscano et al. reported modified *N,O*-bis-acylated hydroxylamine derivatives with arenesulfonyl leaving groups that can produce HNO nonenzymatically under physiological conditions.⁸³ However, mechanistic studies revealed that the chemistry of decomposition is more complicated than originally expected. Acyl migration and amide hydrolysis are two non-HNO producing pathways that compete with nitrosocarbonyl formation and can inhibit HNO release.

Scheme 1-9. Formation of nitrosocarbonyl compounds

Nitrosocarbonyl compounds are reactive molecules that have not yet been isolated in stable form. Using time-resolved infrared (TRIR) spectroscopy, Toscano et al. reported the first direct detection of these reactive intermediates in organic solution.^{47,84} Nitrosocarbonyls were generated by laser photolysis of nitrosocarbonyl photoprecursors, and rate constants were measured for the reaction with amines, thiols, and a diene. It was reported that the mechanism of nitrosocarbonyl reaction with primary amines involved general base catalysis, however, aminolysis by secondary amines was bimolecular. Unlike thiols, thiolates were reported to be very reactive with nitrosocarbonyls on the microsecond time scale, and the mechanism of the reaction was proposed to be through the formation of a detectable tetrahedral intermediate. Based on previous studies of the dienophilic character of nitrosocarbonyls, trapping of a nitrosocarbonyl with 1,3-

cyclohexadiene was monitored by TRIR and the rate constant was measured and reported for the formation of a final Diels-Alder adduct.

Reaction of nitrosocarbonyls with triphenylphosphines was first studied by Kirby and co workers (Scheme 1-10).⁸⁵ The reaction mechanism was proposed to be through deoxygenation following by a rearrangement to form an isocyanate and phosphine oxide. However, the reaction of nitrosoformates with triphenylphosphine turned out to be complicated. Alkoxy groups have low tendency for migration, and upon deoxygenation of the nitrosoformate, alkoxycarbonylnitrenes are proposed to be potentially formed.

Scheme 1-10. Reaction of Nitrosocarbonyls with Triphenylphosphine

In addition to HNO generation, nitrosocarbonyls have attracted attention as potential tools in organic synthesis.⁸⁶⁻¹⁰⁶ Mild aerobic oxidation of hydroxamic acids to generate nitrosocarbonyls has expanded the synthetic utility of these reactive intermediates. Nitrosocarbonyls can react with nucleophiles at the carbonyl carbon to generate HNO. As has been demonstrated recently,⁹³⁻¹⁰⁶ it is also possible for the nucleophile to react at either nitrogen or oxygen through a nitrosocarbonyl aldol

reaction. These reactions are nitrosocarbonyl electrophilic reactions, which yield stable end products.

Scheme 1-11. Reaction of Nitrosocarbonyl Intermediates with Nucleophiles

The utility of nitrosocarbonyls as synthetic tools in Diels-Alder reactions, ene reactions, and nitrosocarbonyl aldol reactions has been reported in the preparation of various functionalized molecules. Using the aerobic mild oxidation process for *in situ* generation of nitrosocarbonyls (Scheme 1-12), it is possible to synthesize *N*- or *O*-substituted hydroxamic acid derivatives selectively. Also, synthesis of both α -amino and α -hydroxy carbonyls was reported by starting with hydroxamic acid derivatives that can be further manipulated after formation of *N*- or *O*-substituted hydroxamic acid derivatives.^{93,94}

Scheme 1-12. Recent Advances on α -Functionalization of Carbonyl Groups

N-Selective Nitrosocarbonylaldol Reaction

O-Selective Nitrosocarbonylaldol Reaction

1.3. Current Studies

As mentioned in section 1.2.5., **HAPY** compounds have been reported as excellent HNO precursors with various half-lives. Pyrazolones have been shown to be efficient leaving groups and also are edaravone derivatives. Edaravone (Scheme 1-13) is a potent antioxidant, and is currently in clinical use for treatment of stroke and cardiovascular diseases.^{107,108} Also, as discussed in section 1.2.6., hydrolysis of nitrosocarbonyls is an efficient pathway for HNO generation. Nitrosocarbonyl compounds are important intermediates not only for HNO release, but also as an intermediate that can be used in different synthetic procedures. Here, we have designed and synthesized two novel classes of nitrosocarbonyl precursors, *N*- and *O*-substituted hydroxamic acids with pyrazolone leaving groups (**NHPY** and **OHYPY**).

compounds, Scheme 1-13).^{109,110} These compounds generate nitrosocarbonyls under physiological conditions, which subsequently produce HNO. In addition to gas chromatographic (GC) analysis to quantify the amount of N₂O produced, we have applied ¹H NMR spectroscopy to monitor the decomposition of our newly developed donors at physiological pH and temperature. For the first time, we have found that pyrazolones are efficient nitrosocarbonyl traps, undergoing an *N*-selective nitrosocarbonyl aldol reaction. This trapping reaction has been used to confirm the involvement of nitrosocarbonyls as intermediates in the observed chemistry. Additionally, we have shown that **NHPY** compounds generate nitrosocarbonyls under mild basic conditions in organic solvent, and may therefore also enjoy synthetic utility.

Scheme 1-13. Nitrosocarbonyl Release from NHPY and OHPY Compounds

As mentioned in section 1.2.7, the reactivity of photogenerated nitrosocarbonyl intermediates was previously studied by TRIR spectroscopy, reporting on the photogeneration of these reactive compounds with characteristic IR bands around 1735 cm^{-1} from 9,10-dimethylantracene adducts and 1,2,4-oxadiazole-4-oxide.⁴⁷ Given our observation that pyrazolones are excellent nitrosocarbonyl traps in both aqueous and organic solutions,^{109,110} we tried to examine this reaction by TRIR spectroscopy and compare that to the reaction with amines. Since the nature of the nitrosocarbonyl intermediate RC(O)N=O ($\text{R} = \text{Me}$, OMe , and NMe_2) has a significant effect on its reactivity, we hope to clarify the relative reactivity of different nitrosocarbonyl intermediates by examining their reactions with amines and pyrazolones by TRIR spectroscopy.

Chapter 2.

Development of *N*-Substituted Hydroxamic Acids with Pyrazolone Leaving Groups as Nitrosocarbonyl Precursors

2.1. Abstract

A novel class of nitrosocarbonyl precursors, *N*-substituted hydroxamic acids with pyrazolone leaving groups (**NHPY**), has been synthesized. Under physiological conditions, these compounds generate nitrosocarbonyl intermediates, which upon hydrolysis release nitroxyl (azanone, HNO) in excellent yields. The amount and rate of nitrosocarbonyl generation are dependent on the nature of the pyrazolone leaving groups and significantly on the structural properties of the **NHPY** donors. Pyrazolones have been found to be efficient nitrosocarbonyl traps, undergoing an *N*-selective nitrosocarbonyl aldol reaction. This trapping reaction has been used to confirm the involvement of nitrosocarbonyl intermediates in **NHPY** aqueous decomposition. In addition, **NHPY** compounds are shown to generate

nitrosocarbonyls efficiently under mild basic conditions in organic solvent, and may therefore also enjoy synthetic utility.

2.2. Introduction

Nitroxyl (azanone, HNO) is the one-electron reduced and protonated relative of nitric oxide (NO) that has recently been proposed as a potential alternative to current treatments for cardiac failure.¹⁻⁹ HNO possesses unique physiological properties that affect vasorelaxation and enhancement of cardiac contractility, and may also find use in the treatment of alcoholism and cancer.⁸⁻⁹

HNO is a very reactive molecule that spontaneously dimerizes to yield hyponitrous acid (HON=NOH), which subsequently dehydrates to nitrous oxide (N₂O).¹⁰ Because of this inherent chemical reactivity, donors are needed for the generation and study of HNO. Angeli's salt (**AS**, Figure 2-1) is a well known HNO donor with a relatively short half-life of 2-3 min under physiological conditions.¹¹ Accessing other HNO donors with different release rates under physiological conditions is important to assess the impact that HNO may potentially have on the treatment of diseases. Piloty's acid (**PA**) derivatives,¹² acyloxy nitroso (**AcON**) compounds,¹³ (hydroxylamino)pyrazolone (**HAPY**),^{14,15a} and

(hydroxylamino)barbituric acid (**HABA**) derivatives¹⁶ (Figure 2-1), are among a limited number of physiologically compatible HNO donors with tunable half-lives that have been reported.¹⁷⁻¹⁹ Continued efforts are required to develop other potential HNO donors that can be used under physiological conditions.

Figure 2-1. Representative examples of HNO donors.

One approach that has been used to generate HNO is based on the hydrolysis of nitrosocarbonyl intermediates.²⁰ Nitrosocarbonyls are transient electrophiles that can react with nucleophiles including water to release HNO. These intermediates can be generated by a variety of chemical processes including oxidation of hydroxamic acids, thermal fragmentation of Diels-Alder adducts,²¹⁻²³ photocleavage of 1,2,4-oxadiazole-4-oxides,²⁴ and the rearrangement of nitrocarbenes.²⁵⁻²⁸ In general, these methods are not suitable for HNO generation under physiological conditions. Notable among compounds reported to generate HNO through nitrosocarbonyl hydrolysis are *N,O*-bis-acylated derivatives such as *N,O*-dibenzoyl-*N*-hydroxycyanamide that release HNO under enzymatic or basic conditions.²⁹ Based on this initial work, we reported modified *N,O*-bis-acylated

hydroxylamine derivatives with arenesulfonyl leaving groups that produce nitrosocarbonyls nonenzymatically under physiological conditions.¹⁷ Mechanistic studies revealed that the chemistry of these donors is complicated, and that non-HNO producing pathways (acyl migration and amide hydrolysis) can be dominant. Nitrosocarbonyls have been used as important components in a variety of synthetic approaches.³⁰⁻⁵⁰ Aerobic oxidation of hydroxamic acids under mild conditions that avoid overoxidation of products has been used to generate nitrosocarbonyl intermediates.³³⁻⁵⁰ These reactive species can also be generated via metal catalysis and have been extensively utilized in ene reactions, Diels-Alder reactions, or as electrophiles in nitrosocarbonyl aldol reactions.

Herein, we report a new class of nitrosocarbonyl donors that decompose based on the general strategy shown in Scheme 2-1. *N*-Substituted hydroxamic acids with pyrazolone leaving groups (**NHPY**, shown in Scheme 2-2) are efficient nitrosocarbonyl donors that upon *O*-deprotonation and loss of HX (HX = pyrazolone) generate nitrosocarbonyl intermediates either under physiological conditions or in basic organic solvent. In aqueous solutions, subsequent hydrolysis of the nitrosocarbonyl (Path A) generates a carboxylic acid and HNO in excellent yield. In organic solution, as has been elegantly demonstrated in recent reports,^{37,39,40,44-46,49} nitrosocarbonyl intermediates can react with nucleophiles at the nitrogen of the nitroso group through an *N*-selective nitrosocarbonyl aldol reaction (Path B) to produce *N*-substituted hydroxamic acid adducts. We have observed this same reactivity using pyrazolone traps that have also been used to confirm nitrosocarbonyl generation upon **NHPY** decomposition.

Scheme 2-1. Reactivity of *N*-Substituted Hydroxamic Acids with Good Leaving Groups X

On the basis of previously reported **HAPY** donors,^{14,15a} pyrazolones have been shown to be efficient leaving groups with the rate of **HAPY** decomposition dependent on the nature of the pyrazolone. This observation was utilized to design **HAPY** donors with varying half-lives. In this report, we demonstrate that the rate of nitrosocarbonyl generation from **NHPY** compounds depends both on the nature of the leaving groups and also unexpectedly on the structural properties of the substituted hydroxylamino group as discussed in detail below.

2.3. Result and Discussion

2.3.1. Synthesis

We have developed two general methodologies for the synthesis of **NHPY** derivatives: (1) the reaction of the corresponding brominated pyrazolone (Br-PY) with an *O*-*tert*-butoxycarbonyl protected hydroxamic acid, followed by subsequent acid deprotection (Scheme 2-2, method A); and (2) an *N*-selective nitrosocarbonyl aldol reaction initiated by oxidation of hydroxamic acids in the presence of

pyrazolones (Scheme 2-2, method B). A 50% v/v aqueous ethanol solution enhances the solubility of reactants and potassium carbonate is used to adjust the pH of solution in the range of 7-8 to favor nitrosocarbonyl reaction with the deprotonated pyrazolone.

Scheme 2-2. Strategies for the Synthesis of NHPY Derivatives

We first synthesized **NHPY** donors **1a-b** using the two described methods; yields are reported in Table 2-1. Method A provides **1a-b** in very poor yields, whereas the nitrosocarbonyl aldol reaction affords these precursors in much higher yields (73%-75%). The synthesis of donors **1c-d** via either of two methods resulted in moderate to good yields (48%-71%). Methods A and B gave donors **1e-g** in low to moderate yields (11%-48%). The nitrosocarbonyl aldol reaction (method B) is straightforward, single pot, and scalable; donor **1a** can be prepared on a gram scale

under conditions identical to a 100 mg scale without any significant loss in isolated yield. For future studies, it may be possible to expand this synthetic route to other active enolates that may undergo further synthetic manipulation.

Table 2-1. Synthetic Yields for NHPY Donors

NHPY	R¹	R²	R³	% Yield Method A	% Yield Method
1a	Ph	C(=NOMe)Me	Me	<10	73
1b	Me	C(=NOMe)Me	Me	<10	75
1c	Ph	C(=NOMe)Me	OMe	48	71
1d	Me	C(=NOMe)Me	OMe	50	69
1e	Ph	C(=NOMe)Me	NMe ₂	35	48
1f	Me	C(=NOMe)Me	NMe ₂	38	47
1g	Ph	Me	NMe ₂	11	48

2.3.2. Decomposition under Physiological Conditions

HNO generation following decomposition of the synthesized **NHPY** donors under physiological conditions was explored. Presumably, upon deprotonation of oxygen, a nitrosocarbonyl intermediate and pyrazolone byproduct are formed (Scheme 2-3). As described above, the reactions of nitrosocarbonyls and pyrazolones can be efficient, and therefore there is a competition between the reverse reaction to produce the initial **NHPY** compound and hydrolysis of the nitrosocarbonyl intermediate to generate HNO.

Scheme 2-3. HNO Release Pathway from NHPY Donors

We have recently used 1H NMR spectroscopy to measure half-lives of donor decomposition by quantifying donor and pyrazolone byproduct as a function of time.^{15,16} Based on the distinctive chemical shifts of the methyl groups of the **NHPY** donors and the pyrazolone byproducts, the decomposition of the donors and release of byproducts is easily monitored. Utilizing this assay, the half-lives of **NHPY** donors were determined under physiologically relevant conditions (Table 2-2).

Table 2-2. Half-lives and HNO Yields for NHPY Donors

NHPY	R ¹	R ²	R ³	$t_{1/2}^a$	% HNO ^c
1a	Ph	C(=NOMe)Me	Me	5 days	82 ^d
1b	Me	C(=NOMe)Me	Me	Stable ^b	-
1c	Ph	C(=NOMe)Me	OMe	2 days	104 ^d
1d	Me	C(=NOMe)Me	OMe	4 days	94 ^d
1e	Ph	C(=NOMe)Me	NMe ₂	25 min	> 95 ^e
1f	Me	C(=NOMe)Me	NMe ₂	46 min	> 95 ^e
1g	Ph	Me	NMe ₂	Stable ^b	-

^aDetermined from 1H NMR analysis of the decomposition of 5 mM of the donor in 10% DMSO- d_6 , 10% D₂O, and 80% H₂O, phosphate buffer (0.25 M) with DTPA (0.2 mM), pH 7.4 at 37 °C under argon. ^b Less than 5% decomposition after 2 days. ^c Donors (0.1 mM) were incubated in phosphate buffer (0.25 M) with DTPA (0.2 mM), pH 7.4 at 37 °C under argon. HNO yields are measured either (d) at the half-life of the donor or (e) after complete decomposition of the donor and are reported relative to the standard HNO donor, Angeli's salt, as determined by N₂O headspace analysis (SEM \pm 5%; n = 3).

Based on our previous studies of **HAPY** donors,^{15a} we investigated the effect of the leaving group on **NHPY** donor half-life. As expected, we observe a substantial impact on half-life that is related to the pK_a values of the respective pyrazolone byproducts. For example, pyrazolone **2a** ($R^1 = \text{Ph}$, $R^2 = \text{C}(=\text{NOMe})\text{Me}$) has a pK_a of 6, making it anionic under physiological conditions and consequently a better leaving group compared with pyrazolone **2c** ($R^1 = \text{Ph}$, $R^2 = \text{Me}$) which has a pK_a of 7.6.^{15a} Accordingly, when R^2 is changed from an *O*-methyloxime group (donors **1e-f**) to a methyl group (donor **1g**) the observed half-life increases dramatically from tens of minutes to days (Table 2-2). Exchanging the R^1 group from phenyl to methyl also has a small effect on half-life, consistent with that previously reported for **HAPY** donors.^{15a} Further exploration of **NHPY** derivatives revealed that the R^3 group has a surprisingly large effect on half-life (Table 2-2). The origin of this unexpected effect is examined in more detail below.

Dimerization of HNO and subsequent dehydration provides N_2O , which is a common benchmark for HNO production.¹⁰ Using Angeli's salt as a standard, the relative amounts of N_2O released from the **NHPY** donors were measured via gas chromatography headspace analysis following incubation in pH 7.4 phosphate buffer solutions containing the metal chelator, diethylenetriaminepentaacetic acid (DTPA), at 37 °C under argon. In all examples (Table 2-2), we find that the **NHPY** compounds are excellent HNO donors, even for the very long-lived donors (**1a** and **1c-d**). HNO was confirmed as the source of N_2O from donor **1e** by membrane inlet mass spectrometry (MIMS), which is a useful technique to detect dissolved gases, including HNO, directly in aqueous solutions (Supporting Information).^{51,52}

2.3.3. Mechanistic Studies

Pyrazolone **2c** has been shown to be an effective trap for HNO and nitrosocarbonyl intermediates under physiological conditions.¹⁵ Our proposed mechanism for the decomposition of the **NHPY** class of HNO donors involves initial oxygen deprotonation followed by formation of a nitrosocarbonyl intermediate. Further hydrolysis of this reactive species generates HNO. Based on analogy with HNO and recent reports of nitroso aldol and nitrosocarbonyl aldol reactions,^{15,16,37,39,40,44,46,48-50,53} we examined nitrosocarbonyl aldol reaction using pyrazolone **2c** as an efficient trap for nitrosocarbonyls (Scheme 2-4).

Donor **1e** was incubated in the presence of pyrazolone **2c** and the reaction was followed by ¹H NMR spectroscopy in pH 7.4 phosphate buffer at 37 °C (Supporting Information). Upon decomposition of donor **1e**, we observe efficient trapping of the nitrosocarbonyl intermediate by pyrazolone **2c** through an *N*-selective nitrosocarbonyl aldol reaction to generate **NHPY 1g**.

Scheme 2-4. Nitrosocarbonyl Trapping by Pyrazolone 2c

Although the above findings strongly suggest the formation of a nitrosocarbonyl intermediate, based on Glover's extensive reactivity studies of *bis*-heteroatom-substituted amides,⁵⁴ attack of pyrazolone **2c** at the amide nitrogen of the hydroxamic acid moiety of donor **1e** to form **NHPY 1g** directly may be possible. To eliminate this possibility, *O*-methylated **NHPY 1** was synthesized and its stability in the presence of pyrazolone **2c** was confirmed by ¹H NMR spectroscopy (Scheme 2-5).

Scheme 2-5. Possible Reaction of *O*-Methylated NHPY **1 with Pyrazolone **2c****

2.3.4. Stability Studies

As described previously, decomposition analysis of **NHPY** compounds revealed a surprisingly strong dependence of the R³ group on donor stability. Donors **1a** (R³ = Me), **1c** (R³ = OMe), and **1e** (R³ = NMe₂) all have the same pyrazolone leaving group, but decompose with dramatically different half-lives of 5 days, 2 days, and 25 min, respectively.

Our previous studies determined that **HAPY** decomposition rates are correlated with donor pK_a , confirming a very low barrier for decomposition once the oxyanion is formed.^{15a,55} To determine if the R^3 group has an unexpected impact on the pK_a values of **NHPY** compounds, we evaluated the pK_a of donors **1a**, **1c**, and **1e**. Decomposition of donor **1e** was monitored by examining the growth of the anionic pyrazolone byproduct **2a** ($\lambda = 265$ nm) at pH 7.4 and 37 °C in phosphate buffer as a function of pH (Figure 2-2).^{14,15a} The decomposition rate is pH-dependent, and based on the experimental kinetic data, the pK_a of donor **1e** is estimated to be 10.7. Under these conditions, donor **1c** decomposes slowly, and donor **1a** is observed to be stable for 1 h. Thus, we measured the pK_a values of donor **1a** (10.0) and **1c** (9.1) in 50% (v/v) aqueous ethanol by titration with NaOH solution. These measurements reveal that donors **1a**, **1c**, and **1e** have similar pK_a values. Interestingly, **HAPY** compounds with pK_a values near 10.5 have half-lives of approximately 30 min,^{15a,55} consistent with our results for donor **1e**. In contrast to the **HAPY** compounds (and **1e** ($R^3 = NMe_2$)), the stability of **1a** ($R^3 = Me$) and **1c** ($R^3 = OMe$) suggests a barrier for the decomposition of these donors even after oxyanion formation.

Figure 2-2. Plot of the observed decomposition rates of donor **1e** (20 μM) as a function of pH in 0.25 M phosphate buffer containing 0.2 mM DTPA at 25 $^{\circ}\text{C}$ determined by UV-vis analysis of the growth of the anionic pyrazolone byproduct **2a** ($\lambda_{\text{max}} = 265 \text{ nm}$). The solid curve is the calculated best fit to a sigmoid function.

2.3.4.1. Structural Studies

To explore the origin of the R^3 group's impact on donor stability, we examined **NHPY** structural properties. Resonance structures **A**, **B**, and **C** (Figure 2-3) can be used as a guide to describe the structures of **NHPY** compounds. We assume that nitrosocarbonyl formation should be favored from structures **A** and **C**, but not from structure **B**.

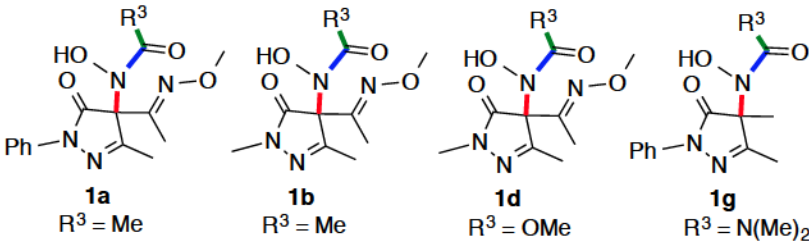

Figure 2-3. Important resonance structures for **NHPY** compounds.

2.3.4.2. X-ray Crystallographic Studies

For **NHPY** compounds **1a**, **1b**, **1d**, and **1g**, we were able to obtain suitable crystals for X-ray diffraction experiments. Distances for the C-N bond (red) between the pyrazolone ring and the hydroxamic acid nitrogen are similar in all cases; however, the N-C(O) bond (blue) distance depends on the electron donating ability of the R³ group (Table 2-3). This bond is shortest for R³ = Me and longest for R³ = NMe₂. The C(O)-R³ bond (green) lengths are similarly impacted by R³. These bond lengths suggest that resonance structure **C** is most important for R³ = NMe₂. The HO-N-C=O dihedral angle of **NHPY 1g** (R³ = NMe₂) (139.4°) is also consistent with resonance structure **C**. On the other hand, the bond length and angles observed for **NHPY 1a** (R³ = Me) and **1b** (R³ = Me) suggest that resonance structure **B** is most important for these precursors. This resonance structure should not favor nitrosocarbonyl generation, and as a result, these donors decompose very slowly (**1a**) or are stable (**1b**) even after deprotonation.

Table 2-3. Selected X-ray Crystallographic Geometry Parameters for NHPY 1a, 1b, 1d, and 1g.

					
NHPY	d _{C-N} (Å)	d _{N-C(O)} (Å)	d _{C(O)-R³} (Å)	d _{C=O} (Å)	< HO-N-C=O (°)
1a	1.459	1.355	1.500	1.229	157.7
1b	1.454	1.349	1.492	1.240	164.0
1d	1.455	1.385	1.335	1.209	157.2
1g	1.471	1.409	1.341	1.238	139.4

2.3.4.3. Computational Studies

To gain additional insight into the structural properties and further compare these with half-life measurements, we calculated the geometries of **NHPY** donors **1a** ($R^3 = \text{Me}$), **1c** ($R^3 = \text{OMe}$), and **1e** ($R^3 = \text{NMe}_2$). All calculations were performed with Spartan '14 at the B3LYP/6-31G(d) level;⁵⁶ optimized geometries and vibrational frequencies were calculated for each compound. Based on the calculated N-C(O) and C(O)- R^3 bond distances and the HO-N-C=O dihedral angles, the degree of pyramidalization at the amide nitrogen is markedly increased in donor **1e** compared with donors **1a** and **1c** (Table 2-4). This result, along with the observed half-lives, suggests that an analysis of the contributions of resonance structures **A** – **C** is a good indicator of the stability of the donors. Donor **1e** ($t_{1/2} = 25$ min), with dominant resonance structure **C**, possesses a pyramidal amide nitrogen and is a much shorter-lived donor compared with donors **1a** ($t_{1/2} = 5$ days) and **1c** ($t_{1/2} = 2$ days). Resonance structure **B**, the major contributor for **NHPY 1a**, does not favor nitrosocarbonyl generation, consistent with the long half-life of this donor.

Table 2-4. Selected B3LYP/6-31G(d) Calculated Geometry Parameters for NHPY 1a, 1c, and 1e

NHPY	$d_{\text{C-N}}$ (Å)	$d_{\text{N-C(O)}}$ (Å)	$d_{\text{C(O)-R}^3}$ (Å)	$d_{\text{C=O}}$ (Å)	$\angle \text{HO-N-C=O}$ (°)
1a	1.470	1.385	1.512	1.222	169.5
1c	1.466	1.394	1.343	1.215	154.7
1e	1.468	1.413	1.369	1.232	136.5

Deprotonation of hydroxyl group is expected to be the first step for decomposition of **NHPY** donors. As mentioned above, donors **1a** and **1c** are still relatively stable to dissociation even after deprotonation. This observation suggests a barrier to decomposition for the oxyanionic species. To gain insight into the stability of anionic **NHPY** compounds, we calculated barriers for dissociation upon deprotonation. Consistent with the results discussed earlier, these calculations indicate the lowest barrier of dissociation for deprotonated **1e** ($R^3 = \text{NMe}_2$) and highest for deprotonated **1a** ($R^3 = \text{Me}$) (Table 2-5), again consistent with the resonance structure discussion above.

Table 2-5. B3LYP/6-31G(d) Calculated Decomposition Barriers for Anionic Donors

NHPY	ΔG^\ddagger (kcal/mol)
1a	11.8
1c	7.9
1e	5.2

The relationship between resonance structures and donor decomposition was further studied by examining the barrier for rotation around HON-C(O) bonds in three model hydroxamic acid derivatives **3a** – **3c** (Figure 2-4). The lowest barriers to rotation around the HON-C(O) bonds for these three model compounds were calculated to be 15, 11.2, and 5.1 kcal/mol, respectively (Supporting Information). This observed trend indicates a correlation between the nature of substituted carbonyl and the rotational barrier.⁵⁷ The highest barrier to rotation for compound **3a** with $R = \text{Me}$ suggests a strong contribution from resonance structure **B** in Figure 2-3. On the other hand, the low barrier to rotation calculated for

compound **3c** with R = NMe₂ suggests a large contribution from resonance structure **C**.

Figure 2-4. Model hydroxamic acid derivatives

2.3.5. Potential Synthetic Utility of NHPY Compounds.

Nitrosocarbonyl compounds have been utilized as versatile electrophiles in a range of synthetic procedures. Recently, mild oxidative pathways to generate nitrosocarbonyls have significantly expanded the scope of their applications. Diels-Alder reactions, ene reactions, and nitrosocarbonyl aldol reactions are examples of useful methodologies that involve nitrosocarbonyl intermediates.^{33-46,48,50}

To demonstrate the potential synthetic utility of **NHPY** compounds, the reaction of donor **1e** with anionic pyrazolone **2d** was examined in organic solvent (dichloromethane) in the presence of 1 equiv of the non-nucleophilic base, diazabicycloundecene (DBU) (Scheme 2-6). After complete decomposition of **NHPY** **1e**, ¹H NMR spectroscopy confirmed the formation of pyrazolone byproduct **2a** and a new *N*-substituted hydroxamic acid adduct **1i** in excellent yield (99%), which was independently synthesized and characterized (Supporting Information). The formation of pyrazolone **1i** is the result of nitrosocarbonyl formation and

subsequent trapping by pyrazolone byproduct **2d**, and can be thought of as a nitrosocarbonyl transfer reaction.

Scheme 2-6. Nitrosocarbonyl Generation from NHPY Compounds in Organic Solvent

*Determined by ¹H NMR analysis of the crude reaction mixture

We also examined a hydroxamic acid derivative that can be further manipulated after completion of the reaction. Donor **1h** generates a nitrosocarbonyl intermediate under mild basic conditions, and in the presence of anionic pyrazolone **2d**, *N*-substituted hydroxamic acid adduct **1j** is formed in good yield (45%) (Scheme 2-6). Acid catalyzed deprotection of the Boc-group leads to the formation of **HAPY-1a** which has previously been reported.¹⁶ These results demonstrate that **NHPY** compounds are efficient nitrosocarbonyl precursors that can be used under mild basic conditions in organic solvent without the need of metal-based catalysts. This non-oxidative protocol importantly avoids any problems associated with product overoxidation.

2.4. Conclusion

The **NHPY** class of nitrosocarbonyl precursors quantitatively generates nitrosocarbonyl intermediates (and ultimately HNO) under physiological conditions with tunable half-lives. The nitrosocarbonyl release rate is dependent on the nature of pyrazolone leaving groups and also significantly on the structural properties of the donors. Under these conditions, pyrazolones are demonstrated to be efficient nitrosocarbonyl traps through an *N*-selective nitrosocarbonyl aldol reaction. This trapping reaction has been used to provide evidence for the involvement of nitrosocarbonyl intermediates in the aqueous decomposition of **NHPY** compounds. Additionally, **NHPY** compounds are shown to release nitrosocarbonyls under mild basic conditions in organic solvent and may enjoy further synthetic applications.

2.5. Experimental

2.5.1. Method and Materials

All starting materials were of reagent grade and used without further purification. 4-(Acetyl-*O*-methoxyoxime)-*N*-phenyl-3-methyl-pyrazolone **2a**, 4-(acetyl-*O*-methoxyoxime)-1,3-dimethylpyrazolone **2b**, 3,4-methyl-*N*-phenylpyrazolone **2c**, 1,3,4-trimethylpyrazolone **2d**,^{15a} brominated pyrazolones (Br-PY),¹⁴ *C*-methoxycarbohydroxamic acid, and *N*-hydroxy-*N*',*N*'-dimethylurea⁵⁸ were prepared according to literature procedures. Acetohydroxamic acid was purchased and used without further purification. NMR spectra were obtained on a 300 or 400 MHz FT-NMR spectrometer. All chemical shifts are reported in parts per million (ppm) relative to residual CHCl₃ (7.26 ppm for ¹H, 77.23 ppm for ¹³C). High-resolution mass spectra were collected on a magnetic sector mass spectrometer working in fast atom bombardment (FAB) mode. Gas chromatography (GC) headspace analysis was performed on the instrument equipped with ECD detection and a packed column. UV-vis absorption spectra were collected using a diode array spectrophotometer.

Method A for the Synthesis of NHPY Compounds: Base (1 equiv) was added to a solution of Boc protected hydroxamic acids (1 equiv) in an appropriate solvent at room temperature and stirred for one hour. The solution was added dropwise to a solution of brominated pyrazolone and stirred for 3 h. The reaction was followed to completion by TLC. The organic solvent was then removed by rotary evaporation, and the **NHPY** product was purified either by column

chromatography (ethyl acetate/hexane) on silica gel or by recrystallization from dichloromethane and hexane.

Method B for the synthesis of NHPY Compounds: Hydroxamic acid (1 – 5 equiv) was added to a solution of pyrazolone (1 equiv) in 50% aqueous ethanol. The pH of the solution was adjusted to 7-8 using 0.2 equiv of potassium carbonate. Sodium periodate (0.5 – 5 equiv) was added to the solution and the reaction mixture was sonicated for 10 min and stirred at room temperature for 3 h until the reaction was complete as determined by TLC. The white solid was removed by filtration and the resulting filtrate concentrated under reduced pressure. Recrystallization from dichloromethane and hexane gave the desired **NHPY** compound.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-acetamide (1a):** According to Method A, triethylamine (0.05 mL, 0.39 mmol) was added to a solution of *N*-(*t*-butoxycarbonyloxy)-acetamide (0.068 g, 0.39 mmol) in acetonitrile (4 mL) at room temperature and the reaction was stirred for 1 h. This solution was added dropwise to 4-(acetyl-*O*-methoxyoxime)-4-bromo-*N*-phenyl-5-methylpyrazolone (0.126 g, 0.39 mmol) and the reaction proceeded at room temperature for 3 h. The reaction was concentrated by rotary evaporation, and the resulting solid was redissolved in dichloromethane and washed with water. The organic phase was collected and concentrated via rotary evaporation. Without further purification, the compound was dissolved in methanol (3 mL), cooled to 0 °C, and acetyl chloride (0.2 mL) was added. The reaction was allowed warm to room temperature and stirred overnight.

The solution was concentrated via rotary evaporation and redissolved in dichloromethane, filtered, and the filtrate was concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (9 mg, 7%).

According to method B, acetohydroxamic acid (0.161 g, 2.14 mmol) was added to a solution of pyrazolone byproduct **2a** (0.105 g, 0.43 mmol) in 50 % aqueous ethanol (7 mL), and potassium carbonate (0.012 g, 0.09 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.458 g, 2.14 mmol) was added to the reaction mixture, sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (10 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation and the resulting solid was redissolved in ethyl acetate (50 mL) and washed three times with a saturated solution of ammonium chloride (30 mL). The organic phase was collected, dried over MgSO₄, filtered, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (0.1 g, 73%).

¹H NMR (400 MHz, CDCl₃) δ: 7.86 (m, 2H), 7.51 (s, 1H), 7.42 (m, 2H), 7.22 (m, 1H), 3.95 (s, 3H), 2.25 (s, 3H), 2.19 (s, 3H), 2.01 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 167.8, 159.0, 157.0, 151.4, 137.8, 128.8, 125.8, 119.5, 76.3, 62.5, 21.0, 15.4, 11.4. HR-MS (FAB): found *m/z* = 319.14094 (MH⁺); calcd for C₁₅H₁₈N₄O₄: 319.14063. Mp: 168-170 °C.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-acetamide (**1b**):** Following the methods described

above for the synthesis of **NHPY 1a** and using 4-(acetyl-*O*-methoxyoxime)-4-bromo-1,3-dimethyl-pyrazolone in method A and pyrazolone **2b** in method B, the title compound was obtained in 8% and 75% yields, respectively, as a white solid.

¹H NMR (400 MHz, CDCl₃) δ: 7.98 (s, 1H), 3.92 (s, 3H), 3.32 (s, 3H), 2.25 (s, 3H), 2.10 (s, 3H), 1.94 (s, 3H). ¹³C NMR (100 MHz, CDCl₃): 169.9, 161.4, 157.0, 151.4, 75.0, 62.5, 31.9, 21.3, 15.5, 11.6. HR-MS (FAB): found *m/z* = 257.12526 (MH⁺); calcd for C₁₀H₁₆N₄O₄: 257.12498. Mp: 171-173 °C.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (1c):** According to method A, sodium hydride 60% (0.061 g, 1.52 mmol) was added to a solution of *N*-(*t*-butoxycarbonyloxy)-methylcarbamate (0.265 g, 1.38 mmol) in dimethylformamide (6 mL) at room temperature and the reaction was stirred for 1 h. This solution was added dropwise to 4-(acetyl-*O*-methoxyoxime)-4-bromo-*N*-phenyl-5-methylpyrazolone (0.447 g, 1.38 mmol) and the reaction proceeded at room temperature for 3 h. The reaction was diluted with ether (10 mL) and washed with ammonium chloride, water, and brine. The organic phase was collected and concentrated via rotary evaporation. Without further purification, the compound was dissolved in methanol (10 mL), cooled to 0 °C, and acetyl chloride (0.6 mL) was added. The reaction was allowed to warm to room temperature and stirred overnight. The solution was concentrated via rotary evaporation and redissolved in dichloromethane, filtered, and the filtrate was concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as

white solid (0.221 g, 48%).

According to method B, to a solution of pyrazolone **2a** (0.245 g, 1 mmol) and *C*-methoxycarbohydroxamic acid (0.109 g, 1.2 mmol) in 50 % aqueous ethanol (5 mL), potassium carbonate (0.028 g, 0.2 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.257 g, 1.2 mmol) was added to the reaction mixture and sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (10 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation, redissolved in ethyl acetate (50 mL), and washed three times with saturated solution of ammonium chloride (30 mL). The organic phase was collected, dried over MgSO₄, filtered, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (0.237 g, 71%).

¹H NMR (400 MHz, CDCl₃) δ: 8.59 (s, 1H), 7.88 (m, 2H), 7.41 (m, 2H), 7.23 (m, 1H), 3.89 (s, 3H), 3.76 (s, 3H), 2.26 (s, 3H), 2.14 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 167.6, 158.3, 158.1, 152.2, 138.0, 128.9, 125.6, 119.6, 76.5, 62.6, 54.5, 16.0, 10.9. HR-MS (FAB): found *m/z* = 335.13550 (MH⁺); calcd. for C₁₅H₁₈N₄O₅: 335.13554. Mp: 160-162 °C.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (1d):** Following the methods described above for the synthesis of **NHPY 1c** and using brominated pyrazolone 4-(acetyl-*O*-methoxyoxime)-4-bromo-1,3-dimethylpyrazolone in method A and pyrazolone **2b** in method B, the title compound was obtained in 50% and 69%

yields, respectively, as a white solid.

^1H NMR (400 MHz, CDCl_3) δ : 7.05 (s, 1H), 3.89 (s, 3H), 3.82 (s, 3H), 3.30 (s, 3H), 2.13 (s, 3H), 2.04 (s, 3H). ^{13}C NMR (100 MHz, CDCl_3) δ : 169.4, 157.9, 157.5, 152.0, 75.4, 62.5, 54.3, 31.9, 15.7, 11.0. HR-MS (FAB): found m/z = 273.11964 (MH^+); calcd. for $\text{C}_{10}\text{H}_{16}\text{O}_5\text{N}_4$: 273.11989. Mp: 162-164 °C.

***N',N'*-Dimethyl-*N*-hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-urea (**1e**):** According to Method A, triethylamine (0.07 mL, 0.5 mmol) was added to a solution of *N*-(*t*-butoxycarbonyloxy)-*N',N'*-dimethylurea (0.102 g, 0.5 mmol) in acetonitrile (6 mL) at room temperature and the reaction stirred for one hour. This solution was added dropwise to 4-(acetyl-*O*-methoxyoxime)-4-bromo-*N*-phenyl-5-methyl-pyrazolone (0.161 g, 0.5 mmol) and the reaction proceeded at room temperature for 3 h. The reaction was concentrated by rotary evaporation, redissolved in dichloromethane, and washed with water. The organic phase was collected and concentrated via rotary evaporation. Without further purification, the compound was dissolved in methanol (7 mL), cooled to 0 °C and acetyl chloride (0.3 mL) was added. The reaction was allowed warm to room temperature and stirred overnight. The solution was concentrated via rotary evaporation, redissolved in dichloromethane, filtered, and the filtrate was concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (61 mg, 35%).

According to method B, to a solution of pyrazolone byproduct **2a** (0.711 g, 2.9 mmol) and *N*-hydroxy-*N',N'*-dimethylurea (0.302 g, 2.9 mmol) in 50 % aqueous

ethanol (15 mL), potassium carbonate (0.08 g, 0.58 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.299 g, 1.4 mmol) was added to the reaction mixture, sonicated for 10 min, and stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (5 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation, redissolved in ethylacetate (40 mL), and washed three times with saturated solution of ammonium chloride (20 mL). The organic phase was collected, dried over MgSO₄, filtered, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (0.483 g, 48%).

¹H NMR (400 MHz, CDCl₃) δ: 7.88 (m, 2H), 7.44 (m, 2H), 7.40 (s, 1H), 7.22 (m, 1H), 3.89 (s, 3H), 3.00 (s, 6H), 2.22 (s, 3H), 2.08 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 171.9, 161.1, 157.0, 152.6, 138.0, 128.8, 125.3, 119.3, 76.2, 62.5, 37.9, 15.56, 11.4. HR-MS (FAB): found *m/z* = 348.16732 (MH⁺); calcd for C₁₆H₂₂N₅O₄: 348.16718. Mp: 140-142 °C.

***N',N'*-dimethyl-*N*-hydroxy-*N*-(3,4-dimethyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-urea (1g):** Following the methods described above for the synthesis of **NHPY 1e** and using 4-bromo-4,5-dimethyl-*N*-phenylpyrazolone in Method A and pyrazolone **2c** in Method B, the title compound was obtained in 11% and 48% yields, respectively, as a white solid.

¹H NMR (400 MHz, CDCl₃) δ: 7.89 (m, 2H), 7.38 (m, 2H), 7.25 (s, 1H), 7.17 (m, 1H), 3.00 (s, 6H), 2.10 (s, 3H), 1.70 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 175.7, 162.8, 161.6, 138.1, 128.8, 124.9, 119.0, 69.6, 38.1, 20.1, 12.7. HR-MS (FAB): found m/z = 291.14536 (MH⁺); calcd for C₁₄H₁₉O₃N₄: 291.14572. Mp: 162-164 °C.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*t*-butylcarbamate (1h):** According to Method B, to a solution of pyrazolone **2a** (0.135 g, 0.55 mmol) and *t*-butylhydroxycarbamate (0.088 g, 0.66 mmol) in 50 % aqueous ethanol (3 mL), potassium carbonate (0.018 g, 0.13 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.141 g, 0.66 mmol) was added to the reaction mixture, sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (6 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation, redissolved in ethylacetate (50 mL), and washed three times with saturated solution of ammonium chloride (30 mL). The organic phase was collected, dried over MgSO₄, filtered, and concentrated *in vacuo*. Recrystallization from dichloromethane and

hexane gave the title compound as white solid. (0.142 g, 69%)

^1H NMR (300 MHz, CDCl_3): 7.92 (m, 2H), 7.40 (m, 2H), 7.19 (m, 1H), 3.87 (s, 3H), 2.26 (s, 3H), 2.13 (s, 3H), 1.38 (s, 9H). ^{13}C NMR (100 MHz, CDCl_3) δ : 166.86, 158.6, 156.9, 152.5, 138.7, 129.0, 124.6, 118.3, 85.7, 76.0, 62.4, 28.2, 15.8, 10.9. HR-MS (FAB): found m/z = 377.18193 (MH^+); calcd for $\text{C}_{18}\text{H}_{24}\text{O}_5\text{N}_4$: 377.18250.

***N',N'*-Dimethyl-*N*-hydroxy-*N*-(1,3,4-trimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-urea (1i):** A solution of pyrazolone **2d** (0.023 g, 0.18 mmol) and 1,8-diazabicycloundec-7-ene (0.027 mL, 0.18 mmol) in 1 mL dichloromethane was stirred for 30 min. The mixture was added to a solution of **NHPY 1e** (0.062 g, 0.18 mmol) in dichloromethane (1 mL). To this solution, diazabicycloundec-7-ene (0.027 mL, 0.18 mmol) was added dropwise and stirred for 4 h at room temperature. The reaction mixture was diluted with 5 mL dichloromethane and washed with HCl 1 N solution. The organic phase was collected, dried over MgSO_4 , and the solvent was removed by rotary evaporation (99% conversion).

According to method B, to a solution of pyrazolone **2d** (0.063 g, 0.5 mmol) and *N*-hydroxy-*N',N'*-dimethylurea (0.052 g, 0.5 mmol) in 50 % aqueous ethanol (5 mL), potassium carbonate (0.014 g, 0.1 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.053 g, 0.25 mmol) was added to the reaction mixture, sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (5 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation, redissolved in ethyl acetate (40 mL), and washed three times with saturated solution of ammonium chloride (20 mL). The

organic phase was collected, dried over MgSO₄, filtered, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid (0.055 g, 48%).

¹H NMR (300 MHz, CDCl₃) δ : 8.36 (s, 1H), 3.29 (s, 3H), 2.97 (s, 6H), 2.00 (s, 3H), 1.53 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ : 177.0, 162.1, 161.4, 68.4, 38.0, 31.4, 19.5, 13.4. HR-MS (FAB): found m/z = 229.13012 (MH⁺); calcd for C₉H₁₆O₃N₄: 229.13007. Mp: 125-127 °C.

***N*-Hydroxy-*N*-(1,3,4-trimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-*t*-butylcarbamate (1j):** A solution of pyrazolone **2d** (0.035 g, 0.28 mmol) and 1,8-diazabicycloundec-7-ene (0.042 mL, 0.28 mmol) in 2 mL dichloromethane was stirred for 30 min. The mixture was added to a solution of **NHPY 1h** (0.105 g, 0.28 mmol) in dichloromethane (2 mL). To this solution, diazabicycloundec-7-ene (0.042 mL, 0.28 mmol) was added dropwise and stirred for 4 h at room temperature. The reaction mixture was diluted with 10 mL dichloromethane and washed with HCl 1 N solution. The organic phase was collected, dried over MgSO₄, filtered, and the solvent was removed by rotary evaporation. The residue was purified by column chromatography (20% ethyl acetate/hexane) on silica gel to obtain the title compound as white solid. (0.032 g, 45%)

According to method B, to a solution of pyrazolone **2d** (0.052 g, 0.41 mmol) and *N*-Boc-hydroxylamine (0.065 g, 0.49 mmol) in 50 % aqueous ethanol (2 mL), potassium carbonate (0.011 g, 0.08 mmol) was added to adjust the pH to 7-8. Sodium periodate (0.105 g, 0.49 mmol) was added to the reaction mixture,

sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (6 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation, redissolved in ethylacetate (30 mL), and washed three times with saturated solution of ammonium chloride (20 mL). The organic phase was collected, dried over MgSO₄, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound as white solid. (0.068 g, 65%)

¹H NMR (300 MHz, CDCl₃) δ : 7.81 (s, 1H), 3.32 (s, 3H), 2.07 (s, 3H), 1.60 (s, 3H), 1.43 (s, 9H). ¹³C NMR (100 MHz, CDCl₃) δ : 175.4, 161.5, 155.1, 77.4, 69.0, 32.0, 28.3, 19.6, 13.1. HR-MS (FAB): found m/z = 258.14549 (MH⁺); calcd for C₁₁H₁₉N₃O₄: 258.14538. Mp: 130-132 °C.

***N,N'*-Dimethyl-*N*-methoxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-urea (compound 1):** According to the method A, sodium hydride 60% (0.016 g, 0.4 mmol) was added to a solution of *N*-methoxy-*N,N'*-dimethylurea (0.042 g, 0.36 mmol) in dimethylformamide (5 mL) at room temperature and the reaction stirred for 1 h. This solution was added dropwise to 4-(acetyl-*O*-methoxyoxime)-4-bromo-*N*-phenyl-5-methyl-pyrazolone (0.116 g, 0.36 mmol) and the reaction proceeded at room temperature for 3 h. The reaction was diluted with ether (8 mL) and washed with ammonium chloride, water, and brine. The organic phase was collected and concentrated by rotary evaporation. The residue was purified by column chromatography (20% ethyl acetate/hexane) on silica gel to obtain the title compound as yellowish oil (0.099 g, 76%).

^1H NMR (400 MHz, CDCl_3) δ : 7.89 (m, 2H), 7.38 (m, 2H), 7.17 (m, 1H), 3.90 (s, 3H), 3.78 (s, 3H), 3.01 (s, 6H), 2.31 (s, 3H), 2.12 (s, 3H). ^{13}C NMR (100 MHz, CDCl_3) δ : 168.6, 158.9, 158.4, 152.1, 138.3, 128.8, 125.0, 119.3, 76.7, 64.0, 62.4, 38.1, 17.3, 12.5. HR-MS (FAB): found m/z = 362.18259 (MH^+); calcd for $\text{C}_{17}\text{H}_{23}\text{N}_5\text{O}_4$: 362.18283.

4-(*N*-Hydroxylamino)-4-methyl-*N*-methyl-3-methylpyrazolone (HAPY-1a): Compound **1j** (32 mg, 0.13 mmol) was dissolved in methanol (3 mL) at 0 °C and acetyl chloride (0.2 mL) was added. The reaction was allowed to warm to room temperature, and stirring was continued overnight. The reaction was concentrated *in vacuo*, redissolved in dichloromethane, filtered, and the filtrate was concentrated via rotary evaporation to give the title compound (71 %, 14 mg), whose characterization was consistent with that previously reported.¹⁵

^1H NMR (400 MHz, DMSO-d_6) δ : 7.51 (d, 1H), 6.25 (d, 1H), 3.10 (s, 3H), 1.98 (s, 3H), 1.00 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ : 175.3, 161.9, 69.0, 30.7, 16.0, 12.7.

***N*-(*t*-Butoxycarbonyloxy)-*N*',*N*'-dimethylurea:** For this synthesis, we modified a procedure that was previously reported.⁵⁹ *N*-Hydroxy-*N*',*N*'-dimethylurea (2.73 mmol, 0.284 g, 1 equiv) and triethylamine (2.73 mmol, 0.38 mL, 1 equiv) in 15 mL acetonitrile were stirred for 1 h at room temperature. Di-*t*-butyl dicarbonate (2.73 mmol, 0.595 g, 1.0 equiv) was added dropwise to the reaction mixture and stirred for 3 h. The reaction was diluted with dichloromethane and washed twice with 1 N HCl solution. The organic phase was dried over MgSO_4 , filtered, and the organic solvent was removed by rotary evaporation, which gave the

title compound as a white solid (0.407 g, 73%).

^1H NMR (400 MHz, CDCl_3) δ : 7.71 (s, 1H), 2.98 (s, 6H), 1.56 (s, 9H). ^{13}C NMR (100 MHz, CDCl_3) δ : 158.0, 154.6, 85.3, 36.2, 27.8. HR-MS (FAB): found m/z = 205.11902 (MH^+); calcd for $\text{C}_8\text{H}_{16}\text{N}_2\text{O}_4$: 205.11883.

***N*-(*t*-Butoxycarbonyloxy)-methylcarbamate:** The synthetic procedure is the same as described above using *C*-methoxycarbohydroxamic acid (0.354 g, 68%).

^1H NMR (400 MHz, CDCl_3) δ : 7.87 (s, 1H), 3.84 (s, 3H), 9.15 (s, 9H). ^{13}C NMR (400 MHz, CDCl_3) δ : 157.5, 153.6, 86.4, 53.9, 27.8. HR-MS (FAB): found m/z = 192.08716 (MH^+); calcd for $\text{C}_7\text{H}_{13}\text{NO}_5$: 192.08720.

***N*-(*t*-Butoxycarbonyloxy)-acetamide:** For this synthesis, we modified a procedure that was previously reported.⁵⁹ Di-*t*-butyl dicarbonate (9.3 mmol, 2.03 g, 1.0 equiv) was added to a suspension of acetohydroxamic acid (9.3 mmol, 0.7 g, 1.0 equiv) in 50 mL of dichloromethane at room temperature. Sodium *t*-butoxide (5.6 mmol, 0.54 g, 0.6 equiv) was added dropwise to the reaction mixture and allowed to stir overnight. The reaction was diluted with dichloromethane and washed twice with saturated NH_4Cl solution. The organic phase was dried over MgSO_4 , filtered, and the organic solvent was removed by rotary evaporation. The resulting solid, without further purification, was used for the synthesis of **NHPY** donors using Method A.

^1H NMR (400 MHz, CDCl_3) δ : 9.87 (s, 1H), 1.52 (s, 9H), 1.45 (s, 3H). ^{13}C NMR (100 MHz, CDCl_3) δ : 158.2, 155.7, 86.2, 31.1, 29.8. HR-MS (FAB): found m/z =

176.09325 (MH⁺); calcd for C₇H₁₃NO₄: 176.09228.

***N*-Methoxy-*N',N'*-dimethylurea:** To a solution of *O*-methylhydroxylamine hydrochloride (46 mmol, 3.84 g, 1 equiv) and potassium carbonate (41.6 mmol, 5.75 g, 0.9 equiv) in 2 mL water and 100 mL ethyl acetate at 0 °C was added (37.2 mmol, 4 g, 0.8 equiv) of dimethylcarbamyl chloride. The reaction mixture was stirred overnight. The solid was filtered off and washed with boiling ethyl acetate. The organic solution was dried over MgSO₄, filtered, and the organic solvent was removed by rotary evaporation, which gave the title compound as colorless oil (3.80 g, 86%).

¹H NMR (400 MHz, CDCl₃) δ: 7.41 (s, 1H), 3.66 (s, 3H), 2.92 (s, 6H). ¹³C NMR (100 MHz, CDCl₃) δ: 160.5, 63.3, 35.7. HR-MS (FAB): found *m/z* = 119.08228 (MH⁺); calcd for C₄H₁₀N₂O₂: 119.08205.

2.7. Supporting Information

2.7.1. Analysis of Nitrous Oxide (N₂O) by Headspace Gas Chromatography.

A gas chromatography instrument equipped with a 1041 injector, electron capture detector, and 2 m x 2 mm x 1/8 in ShinCarbon ST packed column was applied for the analysis of nitrous oxide (N₂O). Grade 5.0 nitrogen was used as both the carrier (8 mL/min) and the make-up (22 mL/min) gas. For all the measurements, the column oven temperature was kept constant at 150 °C, and the injector oven and the detector oven were held at 200 °C and 300 °C, respectively. A 100 µL gastight syringe with a sample-lock was used for all gas injections. Samples were prepared in 6 mL headspace vials with volumes pre-measured for sample uniformity (actual vial volume ranges from 5.8 - 6.3 mL). Vials were charged with 3 mL of phosphate buffer containing the metal chelator, diethylenetriaminepentaacetic acid (DTPA), and fit with rubber septa and 20 mm aluminum seals. The vials were purged with argon and equilibrated for at least 10 minutes at 37 °C in a dry block heater. A 10 mM stock solution of Angeli's salt (AS) was prepared in 10 mM sodium hydroxide, and HNO donors **1a-g** (10 mM) were prepared in acetonitrile and used immediately after preparation. 30 µL of the stock solutions was transferred into vials using a gastight syringe, yielding final concentrations of 0.1 mM. Substrates were then incubated long enough to ensure complete decomposition and equilibration of N₂O with the headspace. For each sample, 60 µL of the headspace was sampled and injected three times using a gastight syringe with a sample lock. The N₂O yield was averaged and reported

relative to the standard, Angeli's salt.

2.7.2. X-ray Crystallographic Data

All reflection intensities were measured at 110(2) K using a diffractometer with either enhance graphite-monochromated Mo $K\alpha$ radiation ($\lambda = 0.71073 \text{ \AA}$) or Cu $K\alpha$ radiation ($\lambda = 1.54178 \text{ \AA}$) equipped with mirror optics. The program CrysAlisPro was used to refine the cell dimensions and for data reduction. The structure was solved with the program SHELXS-2013/SHELXS-2014/7 and was refined on F^2 with SHELXL-2013/SHELXL-2014/7. Empirical absorption correction using spherical harmonics or analytical numeric absorption corrections based on a multifaceted crystal model were applied using CrysAlisPro. The temperature of the data collection was controlled using the system Cryojet. The H atoms were placed at calculated positions (unless otherwise specified) using the instructions AFIX 43 or AFIX 137 with isotropic displacement parameters having values 1.2 or 1.5 times U_{eq} of the attached C atoms. For **NHPY 1a**, the H atoms attached to O2 and O1W (lattice water molecule) were found from difference Fourier maps. Their coordinates and isotropic temperature factors were refined freely. For **NHPY 1b** and **NHPY 1d**, the H atoms attached to O3 were found from difference Fourier maps. Their coordinates and isotropic temperature factor were refined freely. For **NHPY 1g**, the H atoms attached to O2A and O2B were found from difference Fourier maps, and the coordinates were refined freely.

NHPY 1a. Fw = 336.35, colorless block, $0.43 \times 0.37 \times 0.30 \text{ mm}^3$, monoclinic, $P2_1/c$ (no. 14), $a = 12.2766(2)$, $b = 11.1657(3)$, $c = 12.4961(3) \text{ \AA}$, $\beta = 99.727(2)^\circ$, $V = 1688.30(7) \text{ \AA}^3$, $Z = 4$, $D_x = 1.323 \text{ g cm}^{-3}$, $\mu = 0.101 \text{ mm}^{-1}$, abs. corr. range: 0.968–0.977. 12780 Reflections were measured up to a resolution of $(\sin \theta/\lambda)_{\text{max}} = 0.62 \text{ \AA}^{-1}$. 3409 Reflections were unique ($R_{\text{int}} = 0.0374$), of which 2931 were observed [$I > 2 \sigma(I)$]. 233 Parameters were refined. $R1/wR2$ [$I > 2 \sigma(I)$]: 0.0437/0.1157. $R1/wR2$ [all refl.]: 0.0509/0.1199. $S = 1.070$. Residual electron density found between -0.26 and 0.53 e \AA^{-3} . Displacement ellipsoids are given at the 50% probability level.

NHPY 1b. Fw = 256.27, irregular colorless lath, $0.43 \times 0.12 \times 0.08 \text{ mm}^3$, orthorhombic, $Pna2_1$ (no. 33), $a = 9.49728(11)$, $b = 21.3932(2)$, $c = 6.35861(9) \text{ \AA}$, $V = 1291.92(3) \text{ \AA}^3$, $Z = 4$, $D_x = 1.318 \text{ g cm}^{-3}$, $\mu = 0.872 \text{ mm}^{-1}$, abs. corr. range: 0.774–0.947. 8608 Reflections were measured up to a resolution of $(\sin \theta/\lambda)_{\text{max}} = 0.62 \text{ \AA}^{-1}$. 2408 Reflections were unique ($R_{\text{int}} = 0.0208$), of which 2358 were observed [$I > 2 \sigma(I)$]. 172 Parameters were refined using 1 restraint. $R1/wR2$ [$I > 2 \sigma(I)$]: 0.0283/0.0757. $R1/wR2$ [all refl.]: 0.0289/0.0763. $S = 1.046$. Residual electron density found between -0.15 and 0.23 e \AA^{-3} . Displacement ellipsoids are given at the 50% probability level.

NHPY 1d. Fw = 272.27, colorless rod,

 and 0.32 e \AA^{-3} . Displacement ellipsoids are given at the 50% probability level

2.7.3. Membrane Inlet Mass Spectrometry (MIMS) Experiment:

HNO was detected using a MIMS system that consists of a sample cell and membrane probe that has been optimized to detect gases dissolved in aqueous solution. The cell contains rotary blades with an imbedded magnet for efficient stirring past the silastic membrane. The sample cell is also fitted with a heating/cooling jacket for temperature regulation. Both the sample cell and the stock solutions are purged with argon for 10 minutes before the experiment. Injection of 100 μ M of **NHPY** donor **1e** into the MIMS sample cell containing 0.1 M phosphate buffered saline containing 0.1 mM DTPA results in an increase in the m/z 31 (HNO^+) signal.

Figure 2-5. MIMS signal observed at m/z 31 after injection of 100 μ M of **NHPY** donor **1e** to an argon-purged 0.1 M PBS solution pH 7.4 at 37 $^{\circ}$ C with 0.1 mM DTPA.

Scheme 2-7. ^1H NMR Spectroscopy Analysis of Nitrosocarbonyl Trapping by Pyrazolone **2c**

The decomposition of 5 mM of donor **1e** was examined by ^1H NMR spectroscopy in presence of 5 mM of pyrazolone **2c** in 0.25 M phosphate buffer with 0.2 mM DTPA at pH 7.4, 80% H_2O , 10% D_2O , and 10% DMSO-d_6 at 37 °C under argon. Spectra were collected at the start of the experiment and after complete decomposition.

2.7.4. Density Functional Theory (DFT) Calculations

All calculations were performed at the B3LYP/6-31G(d) level using Spartan '14 modeling software.² Geometries were fully optimized and vibrational frequencies were also calculated to verify minimum energy structures (no imaginary frequencies) or transition states (one imaginary frequency) and to provide zero-point vibrational energy corrections.

For neutral and anionic model hydroxamic acid derivatives **3a-b** (Figure S1a), the lowest energy ground states for the *syn* and *anti* conformers (GS1 and GS2, respectively) were calculated. Two transition states, one of which has the nitrogen lone pair *anti* to the carbonyl oxygen (TS1) and the other with the lone pair *syn* (TS2), were examined. For hydroxamic acid **3c** (Figure S2a), three transition states (TS1, TS2, and TS3) were identified that connect the *syn* (GS1) and *anti* (GS2 and GS3) minima. Previous computational investigations of urea derivative have similarly identified three ground states and transition states. For anionic hydroxamic acid derivatives **3a-c** (Figure S1b and S2b), *syn* and *anti* conformers (GS1 and GS2, respectively) and two transition states were calculated (TS1 and TS2).

We also examined the B3LYP/6-31G(d) calculated lowest energy geometries and vibrational frequencies for neutral and anionic NHPY donors **1a**, **1c**, and **1e**. The transition states for nitrosocarbonyl formation from these anionic donors were also calculated.

Figure 2-6. The lowest energy geometries of (a) neutral and (b) anionic hydroxamic acid derivatives **3a** (R = Me) and **3b** (R = OMe) and transition states for C(O)-N bond rotation.

Figure 2-7. The lowest energy geometries of (a) neutral and (b) anionic hydroxamic acid derivative **3c** and transition states for C(O)-N bond rotation.

Chapter 3.

Nitrosocarbonyl Release from *O*-Substituted Hydroxamic Acids with Pyrazolone Leaving Groups

3.1. Abstract

A new class of nitrosocarbonyl precursors, *O*-substituted hydroxamic acids with pyrazolone leaving groups (**OH₂PY**), is described. These compounds generate nitrosocarbonyl intermediates, which upon hydrolysis release nitroxyl (azanone, HNO) under physiologically relevant conditions. Pyrazolones have been used to confirm the generation of nitrosocarbonyls by competitive trapping to form isomeric *N*-substituted hydroxamic acids (**NHPY**) via an *N*-selective nitrosocarbonyl

aldol reaction. The rate of nitrosocarbonyl release from **OHPY** donors is impacted by donor substituents, including the pyrazolone leaving group.

3.2. Introduction

Nitroxyl (azanone, HNO), the one-electron reduced and protonated form of nitric oxide, has been shown to improve both vasorelaxation and myocardial contractility, making HNO donors ideal candidates for drug development.¹⁻⁹ HNO is a reactive molecule that spontaneously dimerizes to produce hyponitrous acid (HON=NOH), which then dehydrates to give nitrous oxide (N₂O).¹⁰ Due to this inherent reactivity, HNO must be generated *in situ* through the use of donor compounds.

Angeli's salt (Na₂N₂O₃, **AS**, Figure 3-1) is a well-known donor that generates HNO under physiological conditions with a short half-life.¹¹ Derivatization of this inorganic salt has been unsuccessful to date, thus preventing modification for tunable HNO release. Piloty's acid (**PA**) derivatives and acyloxy nitroso compounds (**AcON**) represent other types of HNO donors that have been developed with tunable half-lives.¹²⁻¹⁷ Our group has recently reported two new series of HNO

donors with half-lives that can be varied from minutes to hours under physiological conditions: (hydroxylamino)pyrazolone (**HAPY**) and (hydroxylamino)barbituric acid (**HABA**) derivatives.¹⁸⁻²⁰ In addition to these examples, the continued development of efficient HNO donors is important to expand the research tools available to understand the potential role of HNO in biological processes.

Figure 3-1. Some previously reported HNO donors.

Another strategy to release HNO is based on the hydrolysis of nitrosocarbonyl intermediates.²¹⁻²² Nitrosocarbonyls are highly reactive species that can react with nucleophiles including water to generate HNO. Oxidation of hydroxamic acids and thermal decomposition of 9,10-dimethylantracene adducts represent common approaches to nitrosocarbonyl generation.²³⁻²⁵ The photolysis of nitrodiazo compounds, nitronates with alpha leaving groups, and 1,2,4-oxadiazole-4-oxides have also been shown to generate nitrosocarbonyls efficiently.²⁶⁻²⁸ Recently, the aerobic oxidation of hydroxamic acids by metal catalysts under mild conditions has been developed as an efficient strategy for nitrosocarbonyl generation.²⁹⁻⁴⁶ In general, however, the above methods are not suitable for HNO generation under physiological conditions.

Herein, we report a novel class of nitrosocarbonyl donors that upon deprotonation and loss of the leaving group (Scheme 1, HX = pyrazolone) irreversibly generate nitrosocarbonyl intermediates that can hydrolyze to release HNO under physiological conditions. As has been demonstrated in recent reports,^{33,35,36,40-42,45} nitrosocarbonyls can react with nucleophiles through an *N*-selective nitrosocarbonyl aldol reaction to produce *N*-substituted hydroxamic acid adducts. We have recently found that pyrazolones are efficient traps for nitrosocarbonyl intermediates to generate *N*-substituted hydroxamic acid derivatives with pyrazolone leaving groups (**NHPY**) in a reversible manner.⁴⁷ In the current work, we observe this same reactivity upon **OHPY** decomposition to generate nitrosocarbonyls which further react with pyrazolones to produce **NHPY** compounds (Scheme 3-1). We have synthesized and studied **NHPY** compounds independently, and as discussed in Chapter 2, have demonstrated the efficient formation of nitrosocarbonyl intermediates upon decomposition of these compounds.⁴⁷

Scheme 3-1. Reactivity of OHPY nitrosocarbonyl precursors

3.3. Results and Discussion

3.3.1. Synthesis

OHPY compounds **1** have been synthesized by formation of the corresponding bromide (Br-PY) followed by reaction with hydroxamic acids (Scheme 3-2). Initially, **OHPY 1a** was synthesized without the need for chromatographic purification, and its structure was confirmed by X-ray crystallography. The other precursors were purified using column chromatography.

Scheme 3-2. Synthesis of OHPY derivatives

The **OHPY** and **NHPY** isomers can obviously be distinguished by X-ray crystallography. An analysis of ¹³C NMR data and available crystal structures (Supporting Information), reveal that **OHPY** and **NHPY** compounds have distinctive chemical shifts for their quaternary carbons (δ = 87.6 – 90.2 ppm for **OHPY** vs. δ = 68.4 – 76.5 ppm for **NHPY**). Thus, ¹³C NMR spectroscopy conveniently allows the two isomers to be distinguished if crystal structures cannot be obtained.

3.3.2. Decomposition of OHPY compounds

Nitrosocarbonyl formation following **OHPY** decomposition under physiological conditions was studied. As described above, the reaction of nitrosocarbonyls and pyrazolones to produce **NHPY** compounds can be efficient. Upon nitrosocarbonyl generation from **OHPY** precursors **1**, therefore, a competition exists between hydrolysis to generate HNO and carboxylic acid **4** (Scheme 3-3, *Path A*) and trapping by the pyrazolone byproduct **2** to produce **NHPY** compounds **3** (Scheme 3-3, *Path B*). **NHPY** compounds subsequently can also release nitrosocarbonyl intermediates with half-lives that depend on R¹, R², and R³ (Scheme 3.3, *Path C*).⁴⁷

Scheme 3-3. Reactivity of OHPY donors 1

¹H NMR spectroscopy was used to examine the decomposition of **OHPY** donors and measure relative product yields in aqueous solution (Table 3-1).^{19,20} Pyrazolone **2**, **NHPY** **3**, and carboxylic acid **4** are cleanly formed as the only observable organic products. Because **NHPY** compounds **3a**, **3c**, and **3d** all have

half-lives on the order of days,⁴⁷ *Path C* in Scheme 3-3 does not contribute to the observed

chemistry for **OHPY** donors **1a**, **1c**, and **1d**. Thus, the relative yields of pyrazolone **2** and carboxylic acid **4** compared with that for **NHPY** compound **3** in Table 3-1 reflect the competition between *Path A* and *Path B* for these donors.

Table 3-1. Product yields and half-lives for OHPY donors

OHPY	R¹	R²	R³	%2^a	%3^a	%4^a	t_{1/2} (min)^b
1a	Ph	C(=NOMe)Me	Me	74	26	73	25
1b	Ph	Me	Me				Stable ^c
1c	Ph	C(=NOMe)Me	MeO	28	72	27	0.6
1d	Me	C(=NOMe)Me	MeO	14	86	14	1.2
1e	Ph	C(=NOMe)Me	<i>t</i> -BuO	<i>d</i>	<i>d</i>	<i>d</i>	<i>d</i>

^aRelative yields determined from ¹H NMR analysis of the complete decomposition of 0.5 mM of the **OHPY** donor in 10% DMSO-d₆, 10% D₂O, and 80% H₂O, phosphate buffer (0.25 M) containing 0.2 mM of the metal chelator, diethylenetriaminepentaacetic acid (DTPA), pH 7.4 at 37 °C under argon.

^bDetermined by UV-vis spectroscopy. ^cLess than 5% decomposition after 2 days.

^dNot Determined due to low solubility.

OHPY decomposition was also monitored by UV-vis spectroscopy to measure donor half-lives at pH 7.4 and 37 °C (Table 3-1). Based on the chemistry of related HNO donors,^{19,20} we propose that the first step of decomposition is deprotonation which leads to release of nitrosocarbonyl plus pyrazolone. If the barrier to dissociation from anionic **OHPY** is very small, observed half-lives should correlate with donor pK_a and the pyrazolone leaving group.^{19,20} Pyrazolone **2a** (R¹ = Ph, R² =

(C(=NOMe)Me, $pK_a = 6$) is a better leaving group than pyrazolone **2b** ($R^1 = \text{Ph}$, $R^2 = \text{Me}$, $pK_a = 7.6$),¹⁹ consistent with the much shorter half-life for **OHYPY 1a** ($t_{1/2} = 25$ min) compared with **1b** (stable). Exchanging the R^1 group from phenyl to methyl (**OHYPY 1c** vs. **1d**) increases the half-life by a factor of two, consistent with that previously reported for analogous **HAPY** and **NHPY** donors.^{19,47} A comparison of the known pK_a values of the related compounds, PhC(O)NHOH (8.8) and PhOC(O)NHOH (10.0),⁴⁸ indicates that the pK_a of **OHYPY 1a** is likely lower than that of **OHYPY 1c**.

Although these two donors have the same pyrazolone leaving group, the longer half-life for **OHYPY 1a** ($t_{1/2} = 25$ min) compared with **1c** ($t_{1/2} = 0.6$ min) suggests that the barrier to dissociation may also affect the observed half-lives. In the case of **NHYP** donors, the dissociation barrier was found to be strongly dependent on the R^3 group.⁴⁷ The origin and impact of the R^3 group on **OHYPY** dissociation requires further investigation.

HNO generation was examined by gas chromatographic (GC) headspace analysis to quantify the amount of its dimerization product, N_2O , formed following decomposition of **OHYPY** donors in pH 7.4 phosphate buffer solutions at 37 °C (Table 3-2). The amount of HNO release was measured relative to standard HNO donor, Angeli's salt. As expected, HNO yields from **OHYPY** donors are consistent with the corresponding yields of pyrazolone **2** and carboxylic acid **4** observed under the same conditions.

Table 3-2. HNO yields for OHPY donors at different concentrations

OHPY	% HNO ^a		
	500 μ M	100 μ M	20 μ M
1a	70	75	91
1b	<i>b</i>	<i>b</i>	<i>b</i>
1c	20	29	41
1d	8	17	29
1e	<i>c</i>	26	35 ^d

^a HNO yields are measured after complete decomposition of the donor and are reported relative to the standard HNO donor, Angeli's salt, as determined by N₂O headspace analysis (SEM \pm 5%; *n*=3). ^b Stable. ^c Not determined due to low solubility. ^d *t*_{1/2} = 3.2 min (measured using UV-vis spectroscopy).

The competition between nitrosocarbonyl hydrolysis to HNO (*Path A*) and pyrazolone trapping (*Path B*) depends on the relative concentration of pyrazolone. Lower concentrations of pyrazolone **2** following decomposition of lower concentrations of **OHPY 1** will disfavor **NHPY** formation and correspondingly increase the yield of HNO. Determination of HNO yields at different concentrations of donors (Table 3-2), confirms that the yield of HNO is impacted as expected.

3.3.3. Mechanistic Studies

Our proposed mechanism for **OHPY** decomposition involves deprotonation followed by initial formation of a nitrosocarbonyl intermediate. Pyrazolone **2b** has recently been demonstrated to be an efficient trap for nitrosocarbonyls under physiological conditions.⁴⁷ To confirm the formation of nitrosocarbonyls upon **OHPY** decomposition, we incubated **OHPY 1a** (0.5 mM) in presence of pyrazolone **2b** (0.5 mM) in pH 7.4 phosphate buffer at 37 °C (Scheme 3-4). Upon decomposition

of donor **1a** under these conditions, we observe quantitative formation of **NHPY 3b** (Supporting Information), strong evidence for nitrosocarbonyl formation.

Scheme 3-4. Reactivity of OHPY 1a in the presence of pyrazolone 2b

In the absence of pyrazolone **2b**, the decomposition of **OHPY 1a** provides **NHPY 3a** (26%) (which has a half-life of 5 days), and HNO (70%) and acetate (73%) (Scheme 3-4 and Tables 3-1, 3-2). The stability of **NHPY 3a**, along with the observation that it is not formed in the presence of pyrazolone **2b**, also argues against the possibility of a direct intramolecular rearrangement from anionic **OHPY 1a** to **NHPY 3a** without involvement of a nitrosocarbonyl intermediate.

Based on reactivity studies of *bis*-heteroatom-substituted amides,⁴⁹ the formation of **NHPY 3b** may be possible through the direct attack of pyrazolone **2b** on the amide nitrogen of the hydroxamic acid moiety of **NHPY 3a** (Scheme 3-5). To examine this possibility, **NHPY 3a** was incubated with pyrazolone **2b** and its stability was confirmed by ¹H NMR spectroscopy at pH 7.4 and 10. The pK_a of **NHPY**

3a has recently been measured to be 10.0 and its stability at or above pH 10 suggests a relatively high barrier for nitrosocarbonyl formation from this **NHPY** donor even when deprotonated.⁴⁷

Scheme 3-5. The possible reaction of NHPY 3a with pyrazolone 2b

3.4. Conclusions

The **ONHPY** class of nitrosocarbonyl precursors efficiently generates these intermediates under physiological conditions following deprotonation and loss of pyrazolone. The nitrosocarbonyl produced is subsequently hydrolyzed to HNO in competition with trapping by the pyrazolone byproduct via an *N*-selective nitrosocarbonyl aldol reaction to form an isomeric **NHPY** compound. The rate of nitrosocarbonyl release from **ONHPY** compounds in aqueous solution is dependent on the pyrazolone leaving group. This rate is also influenced by the R³ substituent, an effect that is under current investigation.

3.5. Experimental Section

3.5.1. Method and Materials

All starting materials were of reagent grade and used without further purification. *N*-hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-acetamide (**NHPY 3a**), *N*-hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (**NHPY 3c**), *N*-hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (**NHPY 3d**),⁴⁷ 4-(acetyl-*O*-methoxyoxime)-3-methyl-1-phenyl-pyrazolone **2a**, 3,4-dimethyl-1-phenyl-pyrazolone **2b**, 4-(acetyl-*O*-methoxyoxime)-1,3-dimethylpyrazolone **2c**,¹⁹ 4-(acetyl-*O*-methoxyoxime)-4-bromo-3-methyl-1-phenyl-pyrazolone, 4-bromo-3,4-dimethyl-1-phenyl-pyrazolone, 4-(acetyl-*O*-methoxyoxime)-4-bromo-1,3-dimethyl-pyrazolone,¹⁸ *C*-methoxycarbohydroxamic acid, and *tert*-butylhydroxycarbamate⁵⁰ were prepared according to literature procedures. Acetohydroxamic acid was purchased and used without further purification. NMR spectra were obtained on a 400 MHz FT-NMR spectrometer. All chemical shifts are reported in parts per million (ppm) relative to residual CHCl₃ (7.26 ppm for ¹H, 77.23 ppm for ¹³C). High-resolution mass spectra were collected on a magnetic sector mass spectrometer working in fast atom bombardment (FAB) mode. Gas chromatography (GC) headspace analysis was performed on the instrument equipped with ECD detection and a molecular sieve packed column. Ultraviolet-visible (UV-vis) absorption spectra were collected using a diode array spectrophotometer.

3.5.2. Synthesis

General procedure for the synthesis of N-((4-(acetyl-O-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1H-pyrazol-4-yl)oxy)-acetamide (OHPY 1a) and N-((3,4-dimethyl-5-oxo-1-phenyl-4,5-dihydro-1H-pyrazol-4-yl)oxy)-acetamide (OHPY 1b): To a solution of acetohydroxamic acid (1 mmol) in dimethylformamide (3 mL) at room temperature was added sodium hydride, 60 % (1.1 mmol), and the reaction stirred for one hour. This solution was added to a solution of 1 mmol of brominated pyrazolone (4-(acetyl-O-methoxyoxime)-4-bromo-3-methyl-1-phenylpyrazolone for the synthesis of **OHPY 1a** and 4-bromo-3,4-dimethyl-1-phenylpyrazolone for the synthesis of **OHPY 1b**) in dimethylformamide (2 mL), and the reaction proceeded at room temperature for 3 hours. The reaction was diluted with ether (20 mL) and washed with ammonium chloride, water, and brine. The organic phase was collected, dried over magnesium sulfate (MgSO₄), and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave **OHPY 1a** and, following purification by flash chromatography (30% ethyl acetate/hexane) on silica gel, gave **OHPY 1b**.

General procedure for the synthesis of N-((4-(acetyl-O-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1H-pyrazol-4-yl)oxy)-methylcarbamate (OHPY 1c), N-((4-(acetyl-O-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1H-pyrazol-4-yl)oxy)-methylcarbamate (OHPY 1d), and N-(4-(acetyl-O-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1H-pyrazol-4-yl)oxy)-tert-butylcarbamate (OHPY 1e): To a solution of 1 mmol of hydroxamic acid (C-methoxycarbohydroxamic acid for the

synthesis **OHPY 1c** and **1d**, and *tert*-butylhydroxycarbamate for the synthesis of **OHPY 1e**) in acetonitrile (3 mL) at room temperature was added triethylamine (1 mmol), and the reaction stirred for one hour. This solution was added to a solution of 1 mmol of brominated pyrazolone 4-(acetyl-*O*-methoxyoxime)-4-bromo-3-methyl-1-phenyl-pyrazolone for the synthesis of **OHPY 1c** and **1e**, and 4-(acetyl-*O*-methoxyoxime)-4-bromo-1,3-dimethyl-pyrazolone for the synthesis of **OHPY 1d**) in acetonitrile (2 mL), and the reaction proceeded at room temperature for 3 hours. The reaction mixture was concentrated via rotary evaporation, redissolved in dichloromethane, and washed with water and brine. The organic phase was collected, dried over MgSO₄, and concentrated *in vacuo*. The compound was purified by flash chromatography (20% ethylacetate/hexane) on silica gel to give **OHPY 1c**, **1d**, and **1e**.

Synthesis of N-hydroxy-N-(3,4-dimethyl-5-oxo-1-phenyl-4,5-dihydro-1H-pyrazol-4-yl)-N-acetamide (NHPY 3b): To a solution of acetohydroxamic acid (210 mg, 2.80 mmol) and pyrazolone **2b** (105 mg, 0.56 mmol) in 50% aqueous ethanol (7 mL), was added potassium carbonate (12 mg, 0.09 mmol) to adjust the pH to 7-8. Sodium periodate (599 mg, 2.80 mmol) was added to the reaction mixture, which was sonicated for 10 min, and then stirred for 3 h at room temperature. The reaction mixture was diluted with ethanol (12 mL) and the solid was filtered. The filtrate was concentrated via rotary evaporation and the resulting solid was redissolved in ethylacetate (50 mL) and washed three times with a saturated solution of ammonium chloride (30 mL). The organic phase was collected, dried

over MgSO₄, and concentrated *in vacuo*. Recrystallization from dichloromethane and hexane gave the title compound.

3.5.3. Compound Characterization

***N*-((4-(Acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)-acetamide (OHPY 1a):** Colorless crystals, yield 79 mg (25%), m.p. 143-145 °C. ¹H NMR (400 MHz, CDCl₃) δ: 8.96 (1H, s, OH), 7.85-7.83 (2H, m, arom), 7.41-7.38 (2H, m, arom), 7.22-7.20 (1H, m, arom), 3.90 (3H, s, Me), 2.34 (3H, s, Me), 2.06 (3H, s, Me), 1.92 (3H, s, Me). ¹³C NMR (100 MHz, CDCl₃) δ: 167.5, 158.1, 156.7, 150.8, 137.8, 129.1, 125.7, 119.1, 90.2, 62.5, 20.0, 16.4, 10.2. HR-MS (FAB): found *m/z* = 319.14094 (MH⁺); calc. for C₁₅H₁₉N₄O₄: 319.14063.

***N*-((3,4-Dimethyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)-acetamide (OHPY 1b):** White solid, 73 mg (28%), m.p. 142-144 °C. ¹H NMR (400 MHz, CDCl₃) δ: 9.07 (1H, s, OH), 7.90-7.88 (2H, m, arom), 7.44-7.41 (2H, m, arom), 7.23-7.25 (1H, m, arom), 2.34 (3H, s, Me), 1.92 (3H, s, Me), 1.56 (3H, s, Me). ¹³C NMR (100 MHz, CDCl₃) δ: 170.6, 161.3, 158.1, 137.5, 129.1, 125.6, 118.4, 87.6, 20.4, 18.5, 13.2. HR-MS (FAB): found *m/z* = 262.11949 (MH⁺); calc. for C₁₃H₁₅N₃O₃: 262.11917.

***N*-((4-(Acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)-methylcarbamate (OHPY 1c):** White solid, yield 113 mg (34%), m.p. 128-130 °C. ¹H NMR (400 MHz, CDCl₃) δ: 7.92-7.90 (2H, m, arom), 7.50 (1H, s, OH), 7.41-7.44 (2H, m, arom), 7.20-7.22 (1H, m, arom), 3.90 (3H, s, Me), 3.77 (3H, s, Me), 2.38 (3H, s, Me), 2.08 (3H, s, Me). ¹³C NMR (100 MHz, CDCl₃) δ: 166.8,

158.8, 157.3, 151.3, 137.4, 129.2, 125.3, 118.7, 89.8, 62.8, 53.8, 14.9, 10.0. HR-MS (FAB): found m/z = 335.13496 (MH⁺); calc. for C₁₅H₁₉N₄O₅ : 335.13554.

***N*-((4-(Acetyl-*O*-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)-methylcarbamate (OHPY 1d):** White solid, yield 76 mg (28%), ¹H NMR (400 MHz, CDCl₃) δ : 7.52 (1H, s, OH), 3.89 (3H, s, Me), 3.79 (3H, s, Me), 3.28 (3H, s, Me), 2.27 (3H, s, Me), 2.03 (3H, s, Me). ¹³C NMR (100 MHz, CDCl₃) δ: 168.6, 158.3, 157.6, 151.1, 88.9, 62.5, 53.3, 31.4, 15.0, 10.3. HR-MS (FAB): found m/z = 273.12013 (MH⁺); calc. for C₁₀H₁₇N₄O₅ : 273.11989.

***N*-((4-(Acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)-*tert*-butylcarbamate (OHPY 1e):** White solid, yield 139 mg (37%), m.p. 102-104 °C. ¹H NMR (400 MHz, CDCl₃) δ: 7.94-7.92 (2H, m, arom), 7.43-7.40 (2H, m, arom), 7.31 (1H, s, OH), 7.23-7.21 (1H, m, arom), 3.91 (3H, s, Me), 2.36 (3H, s, Me), 2.06 (3H, s, Me), 1.46 (1H, s, C(Me)₃). ¹³C NMR (100 MHz, CDCl₃) δ: 167.3, 159.4, 156.1, 151.2, 137.8, 129.2, 125.3, 118.4, 89.8, 82.9, 62.4, 28.0, 15.1, 10.2. HR-MS (FAB): found m/z = 377.18180 (MH⁺); calc. for C₁₈H₂₅N₄O₅ : 377.18250.

***N*-Hydroxy-*N*-(3,4-dimethyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-acetamide (NHPY 3b):** White solid, yield 107 mg (73%). ¹H NMR (400 MHz, CDCl₃) δ: 9.08 (1H, s, OH), 7.87-7.85 (2H, m, arom), 7.45-7.43 (2H, m, arom), 7.24-7.22 (1H, m, arom), 2.18 (3H, s, Me), 2.10 (3H, s, Me), 1.68 (3H, s, Me). ¹³C NMR (100 MHz, CDCl₃) δ: 167.8, 159.0, 157.2, 137.5, 127.9, 125.8, 119.5, 72.3, 22.5, 19.2, 12.4. HR-MS (FAB): found m/z = 262.11917 (MH⁺); calc. for C₁₃H₁₅N₃O₃ : 262.11981.

3.7. Supporting Information

3.7.1. Analysis of Nitrous Oxide (N₂O) by Headspace Gas Chromatography.

A Varian CP-3800 instrument equipped with a 1041 injector, electron capture detector, and a 25 m 5Å molecular sieve capillary column was applied for the analysis of nitrous oxide (N₂O). Grade 5.0 nitrogen was used as both the carrier (8 mL/min) and the make-up (22mL/min) gas. For all the measurements, the column oven temperature was kept constant at 150 °C, and the injector oven and the detector oven were held at 200 °C and 300 °C, respectively. A 100 µL gastight syringe with a sample-lock was used for all gas injections. Samples were prepared in 6 mL Wheaton Clr headspace vials with volumes pre-measured for sample uniformity (actual vial volume ranges from 5.8 - 6.3 mL). Vials were charged with 3 mL of phosphate buffer containing the metal chelator, diethylenetriaminepentaacetic acid (DTPA), and fit with rubber septa and 20 mm aluminum seals. The vials were purged with argon and equilibrated for at least 10 minutes at 37 °C in a dry block heater. Stock solutions of Angeli's salt (**AS**) were prepared in 10 mM sodium hydroxide, and **OHYPY** donors **1a-e** were prepared in acetonitrile and used immediately after preparation. 30 µL of the stock solutions was transferred into vials using a gastight syringe, yielding final concentrations of 0.5, 0.1, 0.02 mM. Substrates were then incubated long enough to ensure complete decomposition and equilibration of N₂O with the headspace. Depending on the concentration of the donor, 60 or 20 µL of the headspace was sampled and injected three times using a gastight syringe with a sample lock. The N₂O yield was averaged

and reported relative to the AS standard.

3.7.2. Characterization of Compounds:

Pyrazolones, brominated pyrazolones, and *N*-substituted hydroxamic acids with pyrazolone leaving groups (**NHPY** compounds) were synthesized by previously reported methods.

4-(Acetyl-*O*-methoxyoxime)-3-methyl-1-phenylpyrazolone (PY-2a) ¹H NMR (400 MHz, CDCl₃) δ: 7.85 (m, 2H), 7.44 (m, 2H), 7.26 (m, 1H), 3.92 (s, 3H), 2.43 (s, 3H), 2.29 (s, 3H).

3,4-Dimethyl-1-phenylpyrazolone (PY-2b): ¹H NMR (400 MHz, CDCl₃) δ: 7.91 (m, 2H), 7.44 (m, 2H), 7.21 (m, 1H), 2.23 (s, 3H), 1.47 (s, 3H).

4-(Acetyl-*O*-methoxyoxime)-1,3-dimethylpyrazolone (PY-2c): ¹H NMR (400 MHz, CDCl₃) δ: 3.85 (s, 3H), 3.56 (s, 3H), 2.29 (s, 3H), 2.19 (s, 3H).

4-(Acetyl-*O*-methoxyoxime)-4-bromo-3-methyl-1-phenylpyrazolone (PYBr-a): ¹H NMR (400 MHz, CDCl₃) δ: 7.87 (m, 2H), 7.39 (m, 2H), 7.22 (m, 1H), 3.90 (s, 3H), 2.44 (s, 3H), 2.22 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 167.1, 157.2, 151.3, 137.7, 129.1, 125.8, 119.1, 62.7, 56.6, 15.7, 11.7.

4-Bromo-4-methyl-3-methyl-1-phenylpyrazolone (PYBr-b): ¹H NMR (400 MHz, CDCl₃) δ: 7.87 (m, 2H), 7.40 (m, 2H), 7.23 (m, 1H), 2.29 (s, 3H), 1.89 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 169.1, 156.3, 150.7, 138.9, 128.7, 125.6, 120.0, 59.1, 19.1, 11.5.

4-(Acetyl-*O*-methoxyoxime)-4-bromo-1,3-dimethyl-pyrazolone (PYBr-c): ¹H NMR (400 MHz, CDCl₃) δ: 3.85 (s, 3H), 3.32 (s, 3H), 2.25 (s, 3H), 2.18 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 168.7, 156.6, 151.1, 62.1, 55.2, 31.8, 15.2, 11.2.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-acetamide (NHPY 3a):** ¹H NMR (400 MHz, CDCl₃) δ: 7.86 (m, 2H), 7.51 (s, 1H), 7.42 (m, 2H), 7.22 (m, 1H), 3.95 (s, 3H), 2.25 (s, 3H), 2.19 (s, 3H), 2.01 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 167.8, 159.0, 157.0, 151.4, 137.8, 128.8, 125.8, 119.5, 76.3, 62.5, 21.0, 15.4, 11.4.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (NHPY 3c):** ¹H NMR (400 MHz, CDCl₃) δ: 8.59 (s, 1H), 7.88 (m, 2H), 7.41 (m, 2H), 7.23 (m, 1H), 3.89 (s, 3H), 3.76 (s, 3H), 2.26 (s, 3H), 2.14 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 167.6, 158.3, 158.1, 152.2, 138.0, 128.9, 125.6, 119.6, 76.5, 62.6, 54.5, 16.0, 10.9.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-1,3-dimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)-*N*-methylcarbamate (NHPY 3d):** ¹H NMR (400 MHz, CDCl₃) δ: 7.05 (s, 1H), 3.89 (s, 3H), 3.82 (s, 3H), 3.30 (s, 3H), 2.13 (s, 3H), 2.04 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 169.4, 157.9, 157.5, 152.0, 75.4, 62.5, 54.3, 31.9, 15.7, 11.0.

***N*-Hydroxy-*N*-(4-(acetyl-*O*-methoxyoxime)-3-methyl-5-oxo-1-phenyl-4,5-dihydro-1*H*-pyrazol-4-yl)-*t*-butylcarbamate (NHPY 3e):** ¹H NMR (300 MHz, CDCl₃) δ: 7.92 (m, 2H), 7.40 (m, 2H), 7.19 (m, 1H), 3.87 (s, 3H), 2.26 (s, 3H), 2.13 (s,

3H), 1.38 (s, 9H). ^{13}C NMR (100 MHz, CDCl_3) δ : 166.86, 158.6, 156.9, 152.5, 138.7, 129.0, 124.6, 118.3, 85.7, 76.0, 62.4, 28.2, 15.8, 10.9.

Table 3-3. Comparison of ^{13}C NMR Chemical Shifts of the Quaternary Carbons in OHPY and NHPY Compounds

OHPY	R ¹	R ²	R ³	δ (ppm) ^a
1	Ph	C(=NOMe)Me	Me	90.2
2	Ph	Me	Me	87.6
3	Ph	C(=NOMe)Me	MeO	89.8
4	Me	C(=NOMe)Me	MeO	88.9
5	Ph	C(=NOMe)Me	<i>t</i> -BuO	89.8

NHPY	R ¹	R ²	R ³	δ (ppm) ^a
1	Ph	C(=NOMe)Me	Me	76.3
2	Me	C(=NOMe)Me	Me	75.0
3	Ph	Me	Me	72.3
4	Ph	C(=NOMe)Me	MeO	76.5
5	Me	C(=NOMe)Me	MeO	75.4
6	Ph	C(=NOMe)Me	<i>t</i> -BuO	76.0
7	Me	Me	<i>t</i> -BuO	69.0
8	Ph	C(=NOMe)Me	NMe ₂	76.2
9	Me	C(=NOMe)Me	NMe ₂	75.2
10	Ph	Me	NMe ₂	69.6
11	Me	Me	NMe ₂	68.4

^a ^{13}C NMR Chemical shift of the carbon with an asterisk.

3.7.3. X-ray Crystallographic Data

All reflection intensities were measured at 110(2) K using a KM4/Xcalibur (detector: Sapphire 3) with enhance graphite-monochromated Mo $K\alpha$ radiation ($\lambda = 0.71073$ Å) under the program CrysAlisPro (Version 1.171.36.24 Agilent Technologies, 2012). The program CrysAlisPro (Version 1.171.36.24 Agilent Technologies, 2012) was used to refine the cell dimensions. Data reduction was done using the program CrysAlisPro (Version 1.171.36.24 Agilent Technologies, 2012). The structure was solved with the program SHELXS-2013 (Sheldrick, 2013) and was refined on F^2 with SHELXL-2013 (Sheldrick, 2013). Analytical numeric absorption corrections based on a multifaceted crystal model were applied using CrysAlisPro (Version 1.171.36.24 Agilent Technologies, 2012). The temperature of the data collection was controlled using the system Cryojet (manufactured by Oxford Instruments). The H atoms were placed at calculated positions (unless otherwise specified) using the instructions AFIX 43 or AFIX 137 with isotropic displacement parameters having values 1.2 or 1.5 times U_{eq} of the attached C atoms.

OHPY 1a. Fw = 318.33, colorless block, $0.59 \times 0.43 \times 0.38$ mm³, monoclinic, Pc (no. 9), $a = 14.9994(5)$, $b = 12.1027(4)$, $c = 9.3258(3)$ Å, $\beta = 106.778(3)^\circ$, $V = 1620.87(10)$ Å³, $Z = 4$, $D_x = 1.304$ g cm⁻³, $\mu = 0.097$ mm⁻¹,

abs. corr. range: 0.961–0.973. 7785 Reflections were measured up to a resolution of $(\sin \theta/\lambda)_{\max} = 0.65$ Å⁻¹. 3537 Reflections were unique ($R_{\text{int}} = 0.0392$), of which 3362 were observed [$I > 2\sigma(I)$]. 216 Parameters were refined using 2 restraints. $R1/wR2$

$[I > 2\sigma(I)]$: 0.0315/0.0813. $R1/wR2$ [all refl.]: 0.0340/0.0829. $S = 1.056$. Residual electron density found between -0.17 and $0.17 \text{ e } \text{\AA}^{-3}$.

NHPY 3b. 3.7.4. ^1H NMR Spectroscopic Analysis of Nitrosocarbonyl Trapping by Pyrazolone **2b**

The decomposition of 0.5 mM of donor **1a** was examined by ^1H NMR spectroscopy in presence of 0.5 mM of pyrazolone **2b** in 0.25 M phosphate buffer containing 0.2 mM of the metal chelator, diethylenetriaminepentaacetic acid (DTPA), at pH 7.4, 80% H_2O , 10% D_2O , and 10% DMSO-d_6 at 37 °C under argon. Spectra were collected at the start of the experiment and after complete decomposition.

3.7.5. ^1H and ^{13}C NMR Spectra:

Chapter 4.

Reaction of Nitrosocarbonyl Compounds with Pyrazolones as Studied by TRIR Spectroscopy

4.1. Introduction

4.1.1. Nitrosocarbonyl Compounds

Nitrosocarbonyls are transient electrophiles that can react with nucleophiles to generate HNO. The formation of these reactive intermediates was first proposed by pyrolysis of nitrite with aldehydes,¹ and through oxidation of hydroxamic acid derivatives.² Originally, because direct detection of nitrosocarbonyls was difficult, isolation of the end products was used as indicators for nitrosocarbonyl release. For example, upon hydrolysis the formation of carboxylic acid and HNO was used to infer the intermediacy of nitrosocarbonyls.

4.1.2. Nitrosocarbonyls Trapping Reactions

As shown in Scheme 4-1, Kirby and co-workers reported the formation of Diels-Alder adducts upon generation of nitrosocarbonyls in presence of different dienes.³⁻⁵ Further studies have suggested that these Diels-Alder adducts are efficient nitrosocarbonyl precursors under elevated temperature.³

Scheme 4-1. Thermal Generation and Diels-Alder Trapping of Nitrosocarbonyl Compounds.

Upon thermal decomposition of Diels-Alder adducts, Kirby and co-workers studied the reactivity of nitrosocarbonyls with triphenyl phosphine.⁶ It was proposed that through an oxygen atom transfer, triphenyl phosphine oxide and an isocyanate were formed (Scheme 4-2). The mechanism of the reaction was shown to be more complicated than originally expected, and depending on the nature of the nitrosocarbonyl intermediate, different pathways for product generation is possible.

In presence of olefins, nitrosocarbonyls can undergo an ene reaction to yield *N*-substituted hydroxamic acid derivatives (Scheme 4-2).⁷⁻⁹ A limitation with developing nitrosocarbonyl ene reactions has been attributed to the strongly

oxidative conditions often required for nitrosocarbonyl generation which can lead to subsequent product decomposition. Keck¹⁰ and Kirby¹¹ reported a nitrosocarbonyl transfer in the nitrosocarbonyl ene reaction using thermal decomposition of a Diels-Alder adducts, and as the result, the ene adducts were isolated in high yields. Also, Tan and co-workers reported nitrosocarbonyl formation using photoredox catalysis for oxidation of hydroxamic acids.¹² The nitrosocarbonyl ene adducts were isolated in high yields under optimized conditions. Recently, a number of groups have reported mild aerobic conditions for nitrosocarbonyl generation using transition metal catalysis.¹³⁻³⁰ This oxidative protocol is single pot, and can be applied to the ene and Diels-Alder reactions.

Scheme 4-2. Reactivity of Nitrosocarbonyl Compounds

The hydrolysis of nitrosocarbonyls has been used as an efficient pathway for HNO generation. King and co-workers studied the reaction of nitrosocarbonyl compounds with amines resulting in the formation of amides in reasonable yield.³¹ Also, detection of N₂O (the product of HNO dimerization) indicated HNO formation. Another recent report studied the reaction of amines with carbamoyl nitroso intermediates (Scheme 4-3).³² Here, low yields of the expected urea were obtained, and the major product was semicarbazone, which was presumably formed via initial attack at the nitroso nitrogen atom and subsequent dehydration and tautomerization.

Scheme 4-3. Reactivity of Carbamoylnitroso Compounds with Primary Amines

Recently, Read de Alaniz and Yamamoto studied nitrosocarbonyl aldol reaction on the nitrogen and oxygen atoms of nitrosocarbonyls using different carbon based nucleophiles.^{17,18} The regioselectivity and enantioselectivity was shown to be controlled through the use of different catalysts. As has been discussed in Chapters 2 and 3, pyrazolones are efficient nitrosocarbonyl traps, undergoing an *N*-selective nitrosocarbonyl aldol reaction to generate *N*-substituted hydroxamic acid derivatives under physiological conditions.^{33,34} This reaction can be used to confirm the involvement of nitrosocarbonyl intermediates in different reactions.

In the absence of nucleophiles, nitrosocarbonyls may undergo a dimerization reaction, followed by a series of acyl migrations, to release equimolar amounts of N₂O and anhydride (Scheme 4-4).³⁵

Scheme 4-4. Proposed Mechanism for Dimerization of Nitrosocarbonyls in the Absence of Nucleophiles

4.1.3. Detection of Nitrosocarbonyl Intermediates

The spectroscopic detection of nitrosocarbonyls in gas phase was first reported by Schwarz and co-workers using charge reversal and neutralization reionization mass spectrometry.^{36,37} Recently, Toscano et al. reported the direct detection of nitrosocarbonyls using time-resolved infrared (TRIR) spectroscopy.³⁸ This technique is very effective for mechanistic photochemical studies, and provides fundamental information about the structure of reactive intermediates.

To study the reactivity of photogenerated nitrosocarbonyl intermediates, a photoprecursor with high quantum yield is desired. For this purpose, 3,5-diphenyl-1,2,4-oxadiazole-4-oxide was used as an efficient nitrosocarbonyl photoprecursor.³⁹ The reaction of benzonitrile with tertiary amines yields three different products (Scheme 4-5). 3,5-Diphenyl-1,2,4-oxadiazole-4-oxide is one of the products, which

undergoes a photochemical fragmentation in solution to generate equimolar amounts of benzonitrile and nitrosocarbonyl. This nitrosocarbonyl precursor can also undergo thermal cleavage and generate nitrosocarbonyls at elevated temperatures.⁴⁰ Different oxadiazole aryl substitutions are reported to release nitrosocarbonyls following the same decomposition mechanism.³⁹⁻⁴¹

A practical application of photo generated nitrosocarbonyls has been shown in ene reaction using a variety of alkenes.^{39,42} For example, in the synthesis of carbanucleosides, as shown in Scheme 4-6, 3,5-diphenyl-1,2,4-oxadiazole-4-oxide was used as a photo precursor to generate nitrosocarbonyl compounds.⁴² In presence of cyclopentenones functionalized with purine heterobases, diastereomeric mixture of ene adducts were isolated.

Scheme 4-5. Synthesis and Photochemical Fragmentation of Oxadiazole

Scheme 4-6. Ene Reaction of Nitrosocarbonyl Compound with Cyclopentene Derivatives.

Upon 355 nm laser photolysis of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in argon-saturated acetonitrile- d_3 or dichloromethane, Toscano and co-workers observed the bleaching of the oxadiazole at 1310 cm^{-1} using TRIR spectroscopy.³⁸ Also, other bands were observed corresponding to benzonitrile (2265 cm^{-1}) and the nitrosocarbonyl intermediate (1735 , 1590 , 1560 , and 1235 cm^{-1}). In this study, the trapping reaction of the nitrosocarbonyl with diethylamine (DEA) and 1,3-cyclohexadiene (CHD) was monitored to form the corresponding amide and Diels-Alder adduct, respectively, in either acetonitrile- d_3 or dichloromethane.

Scheme 4-7. Reactions of Nitrosocarbonyl Intermediate with Diethylamine and 1,3-Cyclohexadiene

The observed decay rates for the nitrosocarbonyl intermediate in the presence of either DEA or CHD were monitored at 1735 cm⁻¹. Plots of the observed nitrosocarbonyl decay rates versus either concentration of DEA or CHD, which fit well to pseudo-first order rate equations, were used to derive relevant rate constants. Using ($k_{\text{obs}} = k_0 + k_{\text{DEA}}[\text{DEA}]$) and ($k_{\text{obs}} = k_0 + k_{\text{CHD}}[\text{CHD}]$), the second order rate constants $k_{\text{DEA}} = (1.3 \pm 0.5) \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ and $k_{\text{CHD}} = (6.0 \pm 0.5) \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$ were derived.

In another study, upon 266 nm laser photolysis of 9,10-dimethylantracene adducts **1** and **2** (Scheme 4-8), Toscano and co-workers observed a similar IR band at 1735 cm⁻¹, corresponding to nitrosocarbonyl intermediate formation.⁴³ In contrast to **2**, laser photolysis of photoprecursor **1** generated an additional IR band at 1820 cm⁻¹, which formed faster than the time resolution of the spectrometer (ca. 50 ns) and decayed with additional increase of the 1735 cm⁻¹ nitrosocarbonyl band. This band was assigned to the formation of benzoyl radical, potentially generated through either a secondary photolysis of nitrosocarbonyl compound or Norrish type I cleavage of photo precursor **1** to form benzoyl radical along with an NO/DMA adduct that quickly dissociated to NO and DMA. It was proposed that the excited state of **1** could undergo α -cleavage and cycloreversion, and additional formation of the nitrosocarbonyl intermediate was attributed to the recombination of benzoyl radical with NO, which was released from the aminyl radical intermediate. In contrast, photoprecursor **2** proceeded through cycloreversion to generate nitrosocarbonyl (R = Me) compound with no evidence for the acetyl radical formation. Unlike benzoyl nitroside (R = Ph), acetyl nitroside (Me) was not

expected to have absorbance at 266 nm, and it suggested that upon nitrosocarbonyl (R = Ph) release, secondary photolysis was the pathway that occurred to form benzoyl radical and NO. .

Scheme 4-8. Potential Photochemical Decomposition Pathways for 9,10-Dimethylantracene Adducts

Also, the reactivity of photogenerated nitrosocarbonyl compounds (R = Ph, Me, and 4-Cl-Ph) with different primary and secondary amines was reported using 1,2,4-oxadiazole-4-oxides and 9,10-dimethylantracene adducts as nitrosocarbonyl precursors. For primary and secondary amines, the observed decay rates were plotted versus amine concentration, and fit well to $k_{\text{obs}} = k_0 + k_{\text{amine}}[\text{amine}]^2$ and $k_{\text{obs}} = k_0 + k_{\text{amine}}[\text{amine}]$, respectively. This indicated that the aminolysis of nitrosocarbonyls is dependent on the amine structure. The mechanism of nitrosocarbonyl aminolysis by secondary amines was proposed to be bimolecular, however, primary amines reacted with nitrosocarbonyls through a general base catalysis mechanism.

Also, the reactivity of photogenerated nitrosocarbonyl intermediates with thiols was studied. No increase in nitrosocarbonyl decay was observed in presence of a thiol (*N*-acetylcysteine methyl ester). However, addition of DEA to the reaction mixture resulted in faster nitrosocarbonyl decay than in the presence of DEA alone. This result suggested that thiols do not react with nitrosocarbonyls on the microsecond timescale, however, thiolates trap nitrosocarbonyls on the microsecond time scale to form thioesters. As shown in Scheme 4-9, the mechanism was proposed to be through formation of a tetrahedral intermediate, which was detected at 1615 cm⁻¹ by TRIR spectroscopy.

Scheme 4-9. Proposed Mechanism for the Thiolytic of the Nitrosocarbonyl Compound.

4.2. Results and Discussion

4.2.1. Reaction of a Photogenerated Nitrosocarbonyl Compound with Pyrazolones

As mentioned in Chapters 2 and 3, pyrazolones are efficient nitrosocarbonyl traps in both aqueous and organic solutions. We tried to examine this reaction by TRIR spectroscopy and compare it to the reaction with amines. Previously, **PY-1** was reported to be an efficient trap for HNO to form *N*-substituted hydroxylamine derivatives.⁴⁴ Additionally, based on our experiments and consistent with our

expectation, this pyrazolone was shown to be an excellent trap for nitrosocarbonyl intermediates to generate *N*-substituted hydroxamic acid derivatives under physiological conditions.³³ Anionic **PY-1** absorbs light at wavelengths shorter than 300 nm, so it was not possible to use 9,10-dimethylantracene adducts as the nitrosocarbonyl photoprecursor since 266 nm laser photolysis is necessary in this case. However, 3,5-diaryl-1,2,4-oxadiazole-4-oxide can be photolyzed at 355 nm to generate nitrosocarbonyl intermediates. By conducting this photolysis in presence of **PY-1**, we hoped to study the kinetics of this trapping reaction (Scheme 4-10). Also, we hoped to follow the trapping reactions using **PY-2** and **3**, as well as **PY-1**, in order to compare different pyrazolones trapping rate constants with nitrosocarbonyls. Unlike **PY-1**, high concentrations (80 mM) of anionic **PY-2** and **3** absorb light at wavelengths longer than 300 nm. Therefore, the nitrosocarbonyl trapping reaction was studied with only **PY-1** using TRIR spectroscopy.

Scheme 4-10. Suggested Reaction of Photogenerated Nitrosocarbonyl Intermediate with Pyrazolones.

Laser photolysis (355 nm, 5 ns, 2 mJ) of 1 mM 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in acetonitrile produces the TRIR difference spectra shown in Figure 4-1. The observed large positive band at 1738 cm^{-1} corresponds to generation of nitrosocarbonyl (PhC(O)N=O), which is consistent with the previously reported frequency (1735 cm^{-1}) for this intermediate.³⁸

Figure 4-1. TRIR difference spectra averaged over the indicated time frames following laser photolysis (355 nm, 5 ns, 2 mJ) of a solution of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide (1 mM) in argon-saturated acetonitrile.

Based on our previous studies, it was expected that deprotonated pyrazolones should trap nitrosocarbonyls efficiently. To confirm that triethylamine could be used to deprotonate pyrazolones and not interfere with our TRIR experiments, we examined its effect on the rate of nitrosocarbonyl decomposition. Addition of 80 mM triethylamine to a solution of 1 mM 3,5-diphenyl-1,2,4-

oxadiazole-4-oxide in acetonitrile had no effect on kinetic traces observed following 355 nm laser photolysis. This suggests that triethylamine does not react with the nitrosocarbonyl intermediate.

Upon 355 nm laser photolysis of 1 mM 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in presence of 80 mM **PY-1** and 80 mM triethylamine in argon-saturated acetonitrile, the TRIR difference spectra shown in Figure 4-2 were obtained.

Figure 4-2. TRIR difference spectra averaged over the indicated time scales following laser photolysis (355 nm, 5 ns, 2 mJ) of a solution of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide (1 mM), **PY-1** (80 mM), and triethylamine (80 mM) in argon-saturated acetonitrile.

To gain insight into this reaction, spectra from different experiments were overlaid as indicated in Figure 4-3. Spectra observed over the first 1 μ s are similar after laser photolysis of a solution of 1 mM 3,5-diphenyl-1,2,4-oxadiazole-4-oxide with and without added **PY-1**, consistent with the initial formation of a nitrosocarbonyl intermediate. Following nitrosocarbonyl trapping reaction with anionic **PY-1**, it is expected to observe decay of the band at 1738 cm^{-1} band corresponding to a nitrosocarbonyl trapping reaction. Decay of this band, monitored at 1752 cm^{-1} , is observed along with a concomitant growth of the band with the maximum at 1718 cm^{-1} . Comparing the red and green spectra from Figure 4-3 which represent the TRIR difference spectra upon photolysis of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide with and without the presence of anionic **PY-1**, the band monitored at 1752 cm^{-1} is assigned to nitrosocarbonyl intermediate, and its decay is due to nitrosocarbonyl consumption, which is accompanied by concomitant formation of a new product observed with the maximum wavelength at 1718 cm^{-1} . To inhibit the complications due to overlapping spectra of nitrosocarbonyl consumption and product formation at 1718 cm^{-1} , as indicated by red and purple in Figure 4-3, product formation was monitored at 1704 cm^{-1} . Decay of the band due to nitrosocarbonyl consumption was accompanied by the growth of the product at 1704 cm^{-1} with identical kinetics (Figure 4-4).

Figure 4-3. Overlaid of TRIR difference spectra for the indicated conditions and time scales following laser photolysis (355 nm, 5 ns, 2 mJ) of 1 mM solution of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide with and without the presence of 80 mM anionic **PY-1**.

Figure 4-4. Kinetic traces observed following laser photolysis (355 nm, 5 ns, 2 mJ) of 1 mM solution of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide containing 80 mM triethylamine and 80 mM of **PY-1** in argon-saturated acetonitrile at (a) 1752 cm^{-1} and (b) 1704 cm^{-1} . Black curves are the calculated best fit to a single-exponential function.

According to Scheme 4-10, it is expected that the reaction of the nitrosocarbonyl intermediate with anionic **PY-1** will generate **NHPY-1** ($R^1, R^2 = \text{Me}$), and under certain conditions, may also yield **OHPY-1** ($R^1, R^2 = \text{Me}$). To assign the observed IR band with the maximum at 1718 cm^{-1} in Figure 4-2, we synthesized **NHPY-1** and **OHPY-1**, and examined their carbonyl IR frequencies in acetonitrile: **NHPY-1** (1718 and 1650 cm^{-1}) and **OHPY-1** (1722 cm^{-1}). It is expected to observe two IR bands corresponding to two carbonyl groups in **NHPY-1** and **OHPY-1** compounds. However, only one IR band was observed corresponding to carbonyl groups in **OHPY-1**. We suggest that two IR bands corresponding to two carbonyl groups are likely overlapping and experimentally, observed as a single band at 1722 cm^{-1} using acetonitrile as the solvent.

The experimental IR frequencies of these authentic samples suggested that the growth of observed IR bands with the maximum at 1718 cm^{-1} in Figure 4-2, is attributed to the formation of **NHPY-1**, and potentially, **OHPY-1**. It is expected that upon formation of **NHPY-1**, the growth of IR band at 1650 cm^{-1} corresponding to the carbonyl of the hydroxamic acid moiety, may be cancel out by the depletion of the corresponding band in **PY-1**. The decay of nitrosocarbonyl and growth of the product fit well to a single exponential as indicated in Figure 4-4, and as shown the kinetic traces in Figure 4-7, the observed rates were dependent on the concentration of added anionic **PY-1**.

Figure 4-5. Kinetic traces observed following laser photolysis (355 nm, 5 ns, 2 mJ) of 1 mM solution of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in argon-saturated acetonitrile containing triethylamine and **PY-1** with the at 1752 and 1704 cm^{-1} following concentrations: (a) 10 mM (b) 20 mM (c) 40 mM (d) 60 mM. Black curves are the calculated best fit to a single-exponential function.

The observed rates of nitrosocarbonyl decay and the growth of product in acetonitrile versus the concentration of anionic **PY-1** were plotted and fit well to a pseudo-first-order rate equation (Figure 4-8). Applying $k_{\text{obs}} = k_0 + k_{\text{PY}}[\text{PY}]$, the second-order rate constant for reaction of nitrosocarbonyl with anionic **PY-1** was derived, $k_{\text{NC}} = (8.0 \pm 0.5) \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$, which is significantly faster than reported rate constant for the reaction of diethylamine with the same nitrosocarbonyl ($k_{\text{DEA}} = (1.3 \pm 0.5) \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$).³⁸

Figure 4-6. Plots of observed rate of decay of nitrosocarbonyl (indicated with red circles and monitored at 1752 cm^{-1}) and growth of the products (indicated with black circles and monitored at 1704 cm^{-1}) as a function of the concentration of deprotonated **PY-1**.

4.2.2. Product Analysis

Beside TRIR spectroscopy experiments that provide information about the involved intermediates, product studies using HPLC at the endpoint of the reaction were used to gain insight into the identity of the final products. Photolysis of 3,5-

diphenyl-1,2,4-oxadiazole-4-oxide was performed in argon-saturated acetonitrile solutions employing 350 nm irradiation with a Rayonet Reactor. The nitrosocarbonyl trapping ability of **PY-1** was studied in presence and absence of equimolar amounts of triethylamine (Figure 4-6). After photolysis, 20 μ L of the samples was immediately analyzed by HPLC. In both conditions, we observed the formation of benzonitrile along with mixture of **NHPY-1** and **OHPY-1** (Scheme 4-10). We also observed formation of a product with retention time of 7.01 min; its identification is currently under investigation.

NHPY-1 and **OHPY-1** were synthesized ($R^1, R^2 = \text{Me}$ in Scheme 4-7) and used to assign the observed peaks by co-injection. Using these synthesized compounds, the product yields under both conditions were measured and reported in Table 4-1. Results from product analysis of the photolysis of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide (indicated as oxadiazole in Table 4-1 and Figure 4-6) in presence of **PY-1** suggested that both anionic and neutral **PY-1** reacts with nitrogen and oxygen atoms of nitrosocarbonyl intermediate.

Table 4-1. Yield of products following photolysis of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in presence of deprotonated and neutral PY-1 in acetonitrile.

Compounds	NHPY-1 %	OHPY-1 %	PhCN %
Oxadiazole + PY-1 + NEt ₃	47	45	100
Oxadiazole + PY-1	40	53	100

Figure 4-6. HPLC spectra before and after photolysis of 0.4 mM of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in presence of 0.8 mM **PY-1** with (a) 0.8 mM triethylamine and (b) no triethylamine.

To examine the regioselectivity of the transformation to yield either **NHPY** or **OHPY**, we carried out the photolysis in different solvents (Table 4-2). Samples were analyzed by HPLC after photolysis of 0.4 mM 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in presence of 0.5 mM **PY-1** in aqueous acetonitrile, methanol, and dichloromethane.

The results presented in Table 4-2 suggest that the ability of **PY-1** to trap nitrosocarbonyl intermediate is solvent dependent. For example, pyrazolones are excellent nitrosocarbonyl traps in either methanol or acetonitrile; however, only 24% formation of the trapped product is observed in dichloromethane. Due to the low solubility of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in water, a 10% v/v aqueous acetonitrile solution was used as the solvent, and as expected, **PY-1** is observed to be an efficient nitrosocarbonyl trap under these conditions. Interestingly, **NHPY-1** is the major product in aqueous acetonitrile, methanol, and dichloromethane. However, **OHPY-1** is the major product in neat acetonitrile. It seems that the reaction of nitrosocarbonyl compounds with pyrazolones under different solvent conditions is complicated, and more investigations are required to understand and optimize the observed regiochemistry.

Table 4-2. Products Distribution After Photolysis of 3,5-diphenyl-1,2,4-oxadiazole-4-oxide in Presence of PY-1 Using Different Solvents.

Solvent	Trapping	NHPY-1 : OHPY-1
10% Aqueous Acetonitrile	92	85 : 15
Acetonitrile	93	42 : 51
Methanol	100	72 : 28
Dichloromethane	24	100 : 0

4.3. Future Directions

We studied the reactivity of a photogenerated nitrosocarbonyl intermediate with **PY-1** by TRIR spectroscopy, and measured the second-order rate constant for its reaction with the deprotonated **PY-1**, $k_2 = 8 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$. We also characterized the products of this reaction, and interestingly observed formation of both **OHPY-1** and **NHPY-1**, with a product distribution that was dependent on solvent.

Based on discussions in Chapters 2 and 3, the nature of the nitrosocarbonyl intermediate is an important factor that controls its reactivity with pyrazolone nucleophiles. Future TRIR spectroscopy work should involve exploring the photogeneration of different nitrosocarbonyls ($\text{Me}_2\text{NC(O)=O}$, MeOC(O)N=O , and MeC(O)N=O), and examining the reaction of these intermediates with a variety of amines. Because 9,10-dimethylantracene adducts (DMA) are efficient nitrosocarbonyl photoprecursors, we propose to synthesize DMA adducts ($\text{R} = \text{NMe}_2$, OMe , and Me) using literature reported procedures.^{3,45,46} Photolysis of these DMA adducts in presence of amines should make it possible to study the impact of R group (NMe_2 , OMe , and Me) on the reactivity of nitrosocarbonyl intermediates.

4.4. Experimental

4.4.1. Method and Materials

3,5-diaryl-1,2,4-oxadiazole-4-oxide, **NHPY-1**, and **OHPY-1** were synthesized according to previously reported methods.^{33,34,41} NMR spectra were obtained on a 400 MHz FT-NMR spectrometer. All chemical shifts are reported in parts per million (ppm) relative to residual CHCl₃ (7.26 ppm for ¹H, 77.23 ppm for ¹³C). Benzonitrile was purchased from Aldrich and used without further purification.

4.4.2. Characterization of NHPY-1 and OHPY-1:

***N*-hydroxy-*N*-(1,3,4-trimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)benzamide**

(NHPY-1): ¹H NMR (400 MHz, CDCl₃) δ: 9.33 (s, 1H), 7.76 (m, 2H), 7.44 (m, 1H), 7.35 (m, 2H), 3.33 (s, 3H), 2.03 (s, 3H), 1.61 (s, 3H). ¹³C NMR (100 MHz, CDCl₃) δ: 174.8, 167.0, 160.4, 132.3, 131.8, 129.6, 128.1, 69.3, 31.6, 18.8, 12.5. HR-MS (FAB): found *m/z* = 262.11966 (MH⁺); calcd for C₁₃H₁₆O₃N₃: 262.11917.

***N*-((1,3,4-trimethyl-5-oxo-4,5-dihydro-1*H*-pyrazol-4-yl)oxy)benzamide**

(OHPY-1): ¹H NMR (400 MHz, CDCl₃) δ: 7.9 (s, 1H), 7.68 (m, 2H), 7.42 (m, 1H), 7.31 (m, 2H), 3.20 (s, 3H), 2.16 (s, 3H), 1.40 (s, 3H).

4.4.2. Time-Resolved IR Methods

TRIR experiments were performed (with 16 cm^{-1} spectral resolution) following the method of Hamaguchi and co-workers,^{47,48} as has been reported previously.⁴⁹ The broadband output of a MoSi_2 IR source (JASCO) is crossed with excitation pulses from a Continuum Minilite II Nd:YAG laser (355 nm, 5 ns, 2 mJ) operating at 15 Hz. Changes in IR intensity are monitored using an AC-coupled mercury/cadmium/tellurium (MCT) photovoltaic IR detector (Kolmar Technologies, KMPV11-J1/AC), amplified, digitized with a Tektronix TDS520A oscilloscope, and collected for data processing. The experiment is performed in dispersive mode with a JASCO TRIR 1000 spectrometer.

Chapter 5.

Miscellaneous

5.1. Phosphine Reactivity with Nitrosocarbonyl Compounds

5.1.1. Reaction of HNO with Phosphines

HNO represents the smallest nitroso compound. It is a very reactive molecule and dimerizes ($k = 8 \times 10^6 \text{ M}^{-1}\text{s}^{-1}$) to hyponitrous acid (HON=NOH), which subsequently dehydrates to produce nitrous oxide (N_2O).¹ Detection of N_2O has been used as a benchmark of HNO formation. HNO reacts with thiols to yield either disulfides or sulfinamides,^{2,3} and the biological effects of HNO are mostly attributed to its unique reactivity with protein thiols.⁴ Also, metalloproteins redox reactions with HNO is a known trapping pathway, for example, the reaction of HNO with metmyoglobin occurs through reductive nitrosylation reaction to produce NO-myoglobin.⁵

Phosphines, as soft nucleophiles, react with HNO to form chemically distinct products. Preliminary experiments by King and co-workers confirmed formation of triphenylphosphine oxide and aza-ylide after treatment of triphenylphosphine with Angeli's salt in organic/aqueous solutions.⁶ The aza-ylide may undergo hydrolysis to yield triphenylphosphine oxide over longer periods of time. (4,6-Dimethyl-3-sulfonatophenyl)phosphine trisodium salt hydrate (TXPTS) is a water soluble phosphine, and was employed to study the HNO reactivity with phosphines in aqueous solutions (Scheme 5.1). Applying mass spectrometry and ³¹P NMR, King and co-workers reported the formation of aza-ylide and phosphine oxide, as the only detectable products. Additionally, the stability of TXPTS-derived aza-ylide was confirmed using ³¹P NMR. The addition of TXPTS to Angeli's salt was found to quench N₂O formation up to 90%, which also suggested efficient trapping of HNO, and the potential application of TXPTS as an indicator for HNO detection. To rule out the general TXPTS trapping ability of HNO, different HNO precursors were treated with TXPTS. Upon treatment of ¹⁵N labeled para-bromo Piloty's acid, a known HNO precursor, with TXPTS, the formation of aza-ylide was observed by ¹⁵N NMR spectroscopy. Also, the formation of aza-ylide was also observed following incubation of horseradish peroxidase (HRP) with hydrogen peroxide in presence of hydroxylamine and addition of TXPTS.^{7,8}

Scheme 5-1. Reaction of HNO with TXPTS.

The mechanism for the generation of aza-ylide and phosphine oxide is proposed to occur through formation of a hetero three-membered ring intermediate.⁶ Upon reaction of phosphines with either the nitrogen or oxygen atom of HNO, it is expected that zwitterions with structures indicated in Scheme 5-1 are formed. These species are in resonance with a hetero three-membered ring intermediate, which upon addition of a second phosphine, will form equimolar amounts of phosphine oxide and aza-ylide. Based on ³¹P NMR competition experiments with GSH, King and co-workers reported the reaction of TXPTS with HNO to be a second order reaction with a rate constant of $9 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$.⁷ Also, Toscano et al. reported an efficient ¹H NMR assay to monitor HNO trapping by TXPTS, which was based on distinctive chemical shifts of TXPTS, aza-ylide and phosphine oxide.⁹ Thus, formation of aza-ylide can be used as a selective marker for HNO detection in different reactions.

5.1.2. Reaction of C-Nitroso Compounds with Phosphines

C-nitroso compounds are known to react with phosphines in organic solvents to release phosphine oxides and different nitrogenous products.^{10,11} Cadogen reported formation of azoxybenzene and triphenylphosphine oxide, upon treatment of nitrosobenzene with triphenyl phosphine in benzene.¹² The mechanism was complicated and suggested to involve nitrene intermediates. Kirby and co-workers for the first time studied the reaction of nitrosocarbonyls with phosphines.¹³ 9,10-Dimethyl anthracene adducts were used as source of nitrosocarbonyl intermediates, and were treated with triphenyl phosphine in organic solvents at high temperature. After complete decomposition of the nitrosocarbonyl precursor, 9,10-dimethyl anthracene, triphenyl phosphine oxide, and phenyl isocyanate were observed as the products. The generation of isocyanate was proposed to be through the pathway indicated in Scheme 5-2, and its formation was confirmed by its reaction with aniline. Also, in presence of excess triphenyl phosphine, isolation of RCON=PPh_3 suggested the intermediacy of nitrenes.

Kirby and co-workers also studied the reaction of nitrosoformates with phosphines,¹⁴ which in contrast to acylnitroso intermediates, do not produce isocyanate. Due to low migratory tendency of alkoxy groups, it was suggested that alkoxycarbonylnitrenes were formed upon deoxygenation of intermediate **2**, as indicated in Scheme 5-2.

Scheme 5-2. Reaction of Nitrosocarbonyl Compounds with Phosphines

5.1.3. Reaction of Nitrosocarbonyl Compounds with Phosphines under Physiological Conditions

Phosphines are known to be efficient traps for HNO under physiological conditions and have been used as selective tools for HNO detection.⁹ As discussed in section 5.1.2, the mechanism of nitrosocarbonyl reaction with phosphines in presence of organic solvents is complicated, and more investigations are required to confirm the formation of nitrenes and other intermediates. By studying the reactivity of nitrosocarbonyls with phosphines under physiologically relevant conditions, we hoped to employ phosphines for nitrosocarbonyl detection. Also, we tried to clarify the reaction mechanism and characterize the products.

As discussed in Chapter 3, **OHPI-1a** is an efficient nitrosocarbonyl precursor under physiological conditions. Upon generation of the nitrosocarbonyl intermediate, there is a competition between hydrolysis (HNO generation) and a nitrosocarbonyl aldol reaction to produce **NHPI-1a** (Scheme 5-3). For example after complete decomposition of 0.5 mM of **OHPI-1a**, the yields of final products are 74% **PI-1**, 26% **NHPI-1a**, and 73% acetate. Based on our discussions in Chapter 3,

higher concentrations of pyrazolone byproducts following decomposition of higher concentrations of **OHPY** donors will favor **NHPY** formation.

Scheme 5-3. Decomposition of OHPY-1a with/without the Presence of TXPTS

To study the reaction of phosphines with nitrosocarbonyls, we incubated 1 mM **OHPY-1a** with 5 mM TXPTS at pH 7.4 and 37 °C. Upon completion of the reaction, no formation of N_2O was observed by GC headspace analysis. However, TXPTS can react with HNO directly, so from this experiment it was not possible to conclude that the nitrosocarbonyl reacted with TXPTS. Additionally, no formation of **NHPY-1a** was observed by ^1H NMR spectroscopy after complete decomposition of the donor, which strongly suggests the trapping of nitrosocarbonyl intermediate by TXPTS (Figure 5-1).

Figure 5-1. Representative ^1H NMR spectra after complete decomposition of **OHPY-1a** (a) with (b) without the presence of TXPTS under argon at pH 7.4 and 37 $^\circ\text{C}$.

Based on ^{31}P NMR spectroscopy experiments, TXPTS and TXPTS oxide were found to be the only phosphorous containing compound in the reaction mixture. Formation of equimolar amounts of **PY-1a** and phosphine oxide along with 30% acetate was confirmed after complete decomposition of **OHPY-1a** by ^1H NMR spectroscopy (Figure 5-1). The formation of acetate is presumably the result of initial formation of an azoxy compound (as is reported previously in literature for reaction of nitrosobenzene and phosphines), followed by an acyl migration and hydrolysis (Scheme 5-4). Also, growth of two peaks with chemical shifts at 2.58 and 2.57 ppm were observed (Figure 5-1), which corresponds to generation of 30% and 40% of products. We propose that the peak with the chemical shift of 2.57 ppm may correspond to methylamine, which forms through the mechanism indicated in Scheme 5-4. Initial nucleophilic attack of phosphine on oxygen atom of the nitrosocarbonyl is consistent with previously reported nitrosobenzene reactions

with phosphines. Upon methyl migration, the isocyanate formed may undergo hydrolysis to release methylamine and carbon dioxide. The identity of the peak at 2.58 ppm is still under investigation.

Scheme 5-4. Proposed Mechanism for Nitrosocarbonyl Reaction with TXPTS Under Physiological Conditions

In general, the reaction of phosphines with nitrosocarbonyls is complicated, and this reactivity is expected to be dependent on the structure of nitrosocarbonyl intermediate.

5.2. Synthesis of *N*-Substituted Hydroxamic Acids with Barbituric Acids Leaving Groups.

Recently, Toscano et al. introduced a series of *N*-substituted hydroxylamines with barbituric acid leaving groups (**HABA**) with various half-lives and excellent HNO yields. The synthesis of **HABA** derivatives is based on the HNO aldol reaction using Angeli's salt in presence of barbituric acids. This methodology is very efficient, but requires an HNO precursor to generate HNO, which is further trapped by barbituric acid derivatives to form the final HABA compounds. The product yield is mainly dependent on the structure of barbituric acid byproducts. For example, barbituric acids substituted with bulky groups significantly decrease the product yield. In Chapter 2, the single pot nitrosocarbonyl aldol reaction was introduced for the synthesis of different NHPY compounds. This procedure is straightforward, scalable, and generates products in moderate to high yields (47-75%). This synthetic methodology may also be efficient for the generation of different carbon-based hydroxamic acid derivatives.

We tried to expand nitrosocarbonyl aldol reaction for the synthesis of *N*-substituted hydroxamic acids with barbituric acids leaving groups (**NHBA**). The synthesis was initiated with the oxidation of *t*-butyl-*N*-hydroxycarbamate to generate a nitrosocarbonyl intermediate, which was trapped by barbituric acid derivatives to form NHBA compounds. We could also subsequently generate **HABA** compounds by acid deprotection of the BOC groups.

Scheme 5-5. Nitrosocarbonyl Aldol Reaction of Barbituric Acids

5.3. Experimental

5.3.1. Method and Materials

All starting materials were of reagent grade and used without further purification. Barbituric acid derivatives (BA) were synthesized following previously reported procedures.¹⁵ NMR spectra were obtained on either a 300 or 400 MHz FT-NMR spectrometer. All chemical shifts are reported in parts per million (ppm) relative to residual DMSO (2.5 ppm for ¹H, 39.5 for ¹³C) and methanol (3.31 ppm for ¹H).

5.3.2. ¹H NMR Procedure of OHPY-1a with TXPTS

The ¹H NMR procedure was based on previously reported protocol.⁹ To a solution of 0.25 M phosphate buffer solution containing 10% D₂O and 90% H₂O (1 mL) at pH 7.4 under argon with and without the presence of TXPTS (3.3 mg, 5 mM) was added **OHPY-1a** (10 μL of 100 mM in methanol-d₄). The solution was incubated at 37 °C and an ¹H NMR spectrum using a 400 MHz FT-NMR spectrometer was collected after complete decomposition of **OHPY-1a**.

5.3.3. Synthesis and Characterization of NHBA and HABA Compounds

Barbituric acid (BA) derivative (0.5 mmol) was added to a solution of *t*-butyl-*N*-hydroxycarbamate (0.6 mmol) in 50% aqueous ethanol (2.5 mL). The pH of the solution was adjusted to 7-8 using 0.2 equiv of potassium carbonate. Sodium periodate (0.6 mmol) was added to the solution and the reaction mixture was sonicated for 10 min and stirred at room temperature for one hour. The reaction mixture was diluted with 25 mL of ethanol and filtered. The filtrate was concentrated *in vacuo*, and redissolved in ethyl acetate (5 mL). The mixture was washed three times with 20 mL of saturated ammonium chloride, water, and brine. The organic solution was collected, dried over magnesium sulfate, and concentrated *in vacuo*. Crystallization from ether and petroleum ether gave the desired NHBA compound as a white solid.

To a solution of **NHBA** (0.25 mmol) in ethanol (10 mL) was added HCl (2 mL) and stirred overnight. The solution was diluted with ethanol (10 mL), and concentrated *in vacuo*. Crystallization from ether and petroleum ether gave the desired **HABA** compound as a white solid.

tert-Butyl-(5-ethyl-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-1**): White solid, yield 93 mg (65%) , m.p. 167-169 °C. ¹H NMR (300 MHz, DMSO) δ : 11.53 (s, 2H), 9.78 (s, 1H), 2.06 (q, 2H), 1.35 (s, 9H), 0.94 (t, 3H).

tert-Butyl-hydroxy(5-methyl-2,4,6-trioxohexahydropyrimidin-5-yl)carbamate (**NHBA-2**):): White solid, yield 94 mg (69%), m.p. 187-189 °C. ¹H NMR (300 MHz, DMSO) δ : 11.46 (s, 2H), 9.81 (s, 1H), 1.60 (s, 3H), 1.33 (s, 9H). NMR (100 MHz, DMSO-*d*₆) δ : 171.45, 150.03, 81.82, 66.52, 28.20, 21.89. . HR-MS: found m/z = 296.08560 (MNa⁺); calc. for C₁₀H₁₅N₃O₆Na⁺: 296.08531.

tert-Butyl-hydroxy(5-isopropyl-2,4,6-trioxohexahydropyrimidin-5-yl)carbamate (**NHBA-3**): White solid, yield 96 mg (64%), m.p. 177-180 °C. ¹H NMR (300 MHz, DMSO) δ : 11.44 (s, 2H), 9.65 (s, 1H), 2.51 (m, 1H), 1.32 (s, 9H), 0.96 (d, 6H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ : 169.85, 150.45, 82.06, 72.88, 33.53, 28.25, 18.28. HR-MS: found m/z = 324.116963 (MNa⁺); calc. for C₁₂H₁₉N₃O₆Na⁺: 324.11661.

tert-Butyl-hydroxy(2,4,6-trioxo-5-(pentan-2-yl)hexahydropyrimidin-5-yl)carbamate (**NHBA-4**): White solid, yield 118 mg (72%), m.p. 158-161 °C. ^1H NMR (300 MHz, DMSO) δ : 11.48 (s, 2H), 9.63 (s, 1H), 2.32 (m, 1H), 1.67 (m, 1H), 1.31 (s, 9H), 1.11 (m, 2H), 1.07 (m, 1H), 0.94 (d, 3H), 0.83 (t, 3H). ^{13}C NMR (100 MHz, DMSO- d_6) δ : 170.43, 150.81, 82.15, 73.08, 38.26, 33.60, 28.20, 21.09, 14.82, 14.28. HR-MS: found m/z = 352.14822 (MNa^+); calc. for $\text{C}_{14}\text{H}_{23}\text{N}_3\text{O}_6\text{Na}^+$: 352.14791.

tert-Butyl-hydroxy(5-isobutyl-2,4,6-trioxohexahydropyrimidin-5-yl)carbamate (**NHBA-5**): White solid, yield 118 mg (75%), m.p. 189-192 °C. ^1H NMR (300 MHz, DMSO) δ : 11.56 (s, 2H), 9.8 (s, 1H), 1.99 (m, 2H), 1.71 (m, 1H), 1.37 (s, 9H), 0.82 (d, 6H). ^{13}C NMR (100 MHz, DMSO- d_6) δ : 170.93, 150.18, 81.92, 69.16, 44.21, 28.24, 24.34, 23.43. HR-MS: found m/z = 338.13232 (MNa^+); calc. for $\text{C}_{13}\text{H}_{21}\text{N}_3\text{O}_6\text{Na}^+$: 338.13232.

tert-Butyl-(5-(*sec*-butyl)-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-6**): White solid, yield 123 mg (78%), m.p. 178-181 °C. ¹H NMR (300 MHz, DMSO) δ: 11.51 (s, 2H), 9.67 (s, 1H), 2.26 (m, 1H), 1.77 (m, 1H), 1.33 (s, 9H), 0.96 (d, 3H), 0.85 (d, 3H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 169.61, 150.42, 82.08, 73.01, 28.21, 27.80, 24.57, 14.27, 12.58. HR-MS: found *m/z* = 338.13255 (MNa⁺); calc. for C₁₃H₂₁N₃O₆Na⁺: 338.13255.

tert-Butyl-(5-allyl-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-7**): White solid, yield 108 mg (72%), m.p. 163-165 °C. ¹H NMR (300 MHz, DMSO) δ: 11.51 (s, 2H), 9.92 (s, 1H), 5.65 (m, 1H), 5.20 (m, 2H), 2.77 (m, 2H), 1.34 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.07, 150.10, 129.90, 121.79, 82.20, 69.44, 28.58, 28.27. HR-MS: found *m/z* = 322.10085 (MNa⁺); calc. for C₁₂H₁₇N₃O₆Na⁺: 322.10085.

tert-Butyl-hydroxy(2,4,6-trioxo-5-(thiophen-3-ylmethyl)hexahydropyrimidin-5-yl)carbamate (**NHBA-8**): White solid, yield 122 mg (69%), m.p. 175-178 °C. ¹H NMR (300 MHz, DMSO) δ: 11.35 (s, 2H), 10.12 (s, 1H), 7.45 (m, 1H), 7.01 (m, 1H), 6.81 (m, 1H), 3.38 (s, 2H), 1.35 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.62, 149.65, 132.97, 129.12, 127.66, 127.13, 82.40, 69.65, 35.93, 28.19. HR-MS: found *m/z* = 378.07320 (MNa⁺); calc. for C₁₄H₁₇N₃O₆SNa⁺: 378.073203.

tert-Butyl-hydroxy(2,4,6-trioxo-5-phenylhexahydropyrimidin-5-yl)carbamate (**NHBA-9**): White solid, yield 119 mg (71%), m.p. 180-183 °C. ¹H NMR (300 MHz, DMSO) δ: 11.72 (s, 2H), 9.50 (s, 1H), 7.45 (m, 5H), 1.37 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 169.02, 149.84, 131.75, 129.94, 129.10, 128.87, 82.32, 74.68, 28.25. HR-MS: found *m/z* = 358.10136 (MNa⁺); calc. for C₁₅H₁₇N₃O₆Na⁺: 358.10096.

tert-Butyl(5-benzyl-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-10**): White solid, yield 140 mg (80%), m.p. 181-183 °C. ¹H NMR (300 MHz, DMSO) δ: 11.26 (s, 2H), 10.07 (s, 1H), 7.29 (m, 3H), 7.06 (m, 2H), 3.37(s, 2H), 1.35 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.70, 149.43, 132.17, 130.36, 128.91, 128.36, 82.17, 70.20, 41.89, 28.21. HR-MS: found *m/z* = 372.11694 (MNa⁺); calc. for C₁₆H₁₉N₃O₆Na⁺: 372.11694.

tert-butyl-(5-(2-chlorobenzyl)-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-11**): White solid, yield 157 mg (82%), m.p. 190-193 °C. ¹H NMR (300 MHz, DMSO) δ: 11.29 (s, 2H), 10.09 (s, 1H), 7.45 (m, 1H), 7.32 (m, 2H), 7.16 (m, 1H), 3.52 (s, 2H), 1.41 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.48, 149.77, 135.01, 133.25, 130.39, 120.29, 130.07, 127.75, 82.37, 70.04, 38.10, 28.26. HR-MS: found *m/z* = 406.07763 (MNa⁺); calc. for C₁₆H₁₈N₃O₆ClNa⁺: 406.07763.

tert-Butyl-(5-(4-chlorobenzyl)-2,4,6-trioxohexahydropyrimidin-5-yl)(hydroxy)carbamate (**NHBA-12**): White solid, yield 134 mg (70%), m.p. °C. ¹H NMR (300 MHz, DMSO) δ: 11.3 (s, 2H), 10.08 (s, 1H), 7.37 (m, 2H), 7.03 (m, 2H), 3.28 (s, 2H), 1.34 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.38, 149.55, 133.17, 132.25, 131.34, 128.92, 82.36, 70.04, 41.06, 28.26. HR-MS: found *m/z* = 406.07763 (MNa⁺); calc. for C₁₆H₁₈N₃O₆ClNa⁺: 406.07763.

tert-Butyl-hydroxy(5-(4-methoxybenzyl)-2,4,6-trioxohexahydropyrimidin-5-yl)carbamate (**NHBA-13**): White solid, yield 148 mg (78%), m.p. 197-200 °C. ¹H NMR (300 MHz, DMSO) δ: 11.24 (s, 2H), 10.03 (s, 1H), 7.01 (m, 2H), 6.90 (m, 2H), 3.24 (s, 2H), 1.32 (s, 9H). ¹³C NMR (100 MHz, DMSO-*d*₆) δ: 170.83, 159.27, 149.54, 131.48, 123.77, 114.32, 82.05, 70.18, 55.50, 41.20, 28.23. HR-MS: found *m/z* = 402.12738 (MNa⁺); calc. for C₁₇H₂₁N₃O₇Na⁺: 402.12717.

(5-(*N*-hydroxylamino)-5-phenylbarbituric acid (**HABA-1**): White solid, yield 47 mg (69%), m.p. 183-185 °C. ^1H NMR (400 MHz, DMSO) δ : 11.76 (s, 2H), 8.60 (br. s, 2H), 7.38 (m, 5H). ^{13}C NMR (100 MHz, DMSO- d_6) δ : 170.17, 149.62, 134.11, 129.34, 128.93, 126.53, 73.14.

5-(*N*-Hydroxylamino)-5-(4-methoxybenzyl)-barbituric acid (**HABA-2**): White solid, yield 66 mg (95%). ^1H NMR (400 MHz, DMSO- d_6) δ : 11.35 (s, 2H), 6.92 (d, 2H), 6.82 (d, 2H), 3.70 (s, 3H), 2.92 (s, 2H). ^{13}C NMR (100 MHz, DMSO- d_6) δ : 171.41, 158.50, 149.36, 130.62, 124.53, 113.90, 71.69, 55.00, 38.45.

5-(*N*-hydroxylamino)-5-(2-thienylmethyl)-barbituric acid (**HABA-3**): White solid, yield 51 mg (70%), m.p. 175-178 °C. ^1H NMR (400 MHz, DMSO- d_6) δ : 11.45 (s, 2H), 8.13 (s, 1H), 7.39 (s, 1H), 6.94 (s, 1H), 6.73 (s, 1H), 6.53 (br. s, 1H), 3.21 (s, 2H). ^{13}C NMR (100 MHz, DMSO- d_6) δ : 171.59, 149.56, 134.24, 127.73, 127.12, 126.02, 71.08, 32.95.

5.5. ^1H NMR and ^{13}C NMR Spectra

4ClBnBA-NBOC

Curriculum Vitae

Saghar Nourian was born in Tehran, Iran on September 16, 1985. Her interest in chemistry started in high school after taking courses in chemistry. In 2003, she enrolled in Sharif University of Technology where she graduated with a B.S. in chemistry. After a brief experience working for a pharmaceutical company, she decided to pursue her education by studying organic chemistry as a Master's student at Sharif University of Technology in 2008. During that time, she performed research under supervision of Professor Firouz Matloubi Moghaddam. She synthesized unique bicyclic systems and α -aminonitrile-type compounds, and it was a beginning for her great interest for science. In 2010, she graduated with her M.S with honor, and decided to follow her education in higher level.

In the fall of 2012, she joined Professor John P. Toscano lab at Johns Hopkins University where her PhD thesis was on the synthesis of precursors and reactivity studies of nitrosocarbonyl intermediates. During her studies as a PhD student, she authored two patent applications and couple of manuscripts. In winter 2017, she was accepted for a three-month internship through Hopkins/MedImmune program, where she worked as a scientist co-op and studied HCPs using different analytical techniques. In July 2017, Saghar received her Doctorate of Philosophy in Chemistry. After receiving her PhD, Saghar will begin a postdoctoral fellowship at NCI/NIH in Fredrick, in the lab of Dr. Martin Schnermann, working on near-IR uncaging chemistry for *in vivo* drug delivery.
